

Preface

Who This Book is For

This book describes the Thor2024 ISA. It is for anyone interested in instruction set architectures.

Motivation

The author desired a CPU core supporting 128-bit floating-point operations for the precision. He also wanted a core he could develop himself. The simplest approach to supporting 128-bit floats is to use 128-bit wide registers, which leads to 128-bit wide busses in the CPU and just generally a 128-bit design. It was not the author's original goal to develop a 128-bit machine. There are good ways of obtaining 128-bit floating-point precision on 64-bit or even 32-bit machines, but it adds some complexity. Complexity is something the author must manage to get the project done and a flat 128-bit design is simpler.

Having worked on Thor2023 for several months, the author finally realized that it did not have very good code density. Thor2022 was better in that regard. So, Thor2024 is a mix of the best from previous designs. Thor2024 aims to improve code density over earlier versions.

Some efficiency is being traded off for design simplicity. Some of the most efficient designs are 32-bit.

The processor presented here isn't the smallest, most efficient, and fastest RISC processor. It's also not a simple beginner's example. Those weren't my goals. Instead, it offers reasonable performance with an easy-to-understand state machine and hopefully design simplicity. It's also designed around the idea of using a simple compiler. Some operations like multiply and divide could have been left out and supported with software generated by a compiler rather than having hardware support. But I was after a simple compiler design. There's lots of room for expansion in the future. I chose a 128-bit design supporting 128-bit ops in part anticipating more than 4GB of memory available sometime down the road. A 128-bit architecture is doable in FPGA's today, although it uses four or more times the resources that a 32-bit design would.

About the Author

First a warning: I'm an enthusiastic hobbyist like yourself, with a ton of experience. I've spent a lot of time at home doing research and implementing several soft-core processors, almost maniacally. One of the first cores I worked on was a 6502 emulation. I then went on to develop the Butterfly32 core. Later the Raptor64. I have about 25 years professional experience working on banking applications at a variety of language levels including assembler. So, I have some real-world experience developing complex applications. I also have a diploma in electronics engineering technology. Some of the cores I work on these days are too complex and too large to do at home on an inexpensive FPGA. I await bigger, better, faster boards yet to come. To some extent larger boards have arrived. The author is a bit wary of larger boards. Larger FPGAs increase build times by their nature.

Nomenclature

There has been some mix-up in the naming of load and store instructions as computer systems have evolved. A while ago, a “word” referred to a 16-bit quantity. This is reflected in the mnemonics of instructions where move instructions are qualified with a “.w” for a 16-bit move. Some machines referred to 32-bits as a word. Times have changed and 64-bit workstations are now more common. In the author’s parlance a word refers to the word size of a machine, which may be 16, 32, 64 bits or some other size. What does “.w” or “.d”, and “.l” refer to? To some extent it depends on the architecture.

The ISA refers to primitive object sizes following the convention suggested by Knuth of using Greek.

Number of Bits		Instructions	Comment
8	byte	LDB, STB	UTF8 usage
16	wyde	LDW, STW	
32	tetra	LDT, STT	
64	octa	LDO, STO	
128	hexi	LDH, STH	

The register used to address instructions is referred to as the instruction pointer or IP register. The instruction pointer is a synonym for program counter or PC register.

Little Endian vs big Endian

One choice to make is whether the architecture is little endian or big endian. There’s a never-ending argument by computer folks as to which endian is better. In reality they are about the same or there wouldn’t be an argument. In a little-endian architecture, the least significant byte is stored at the lowest memory address. In a big-endian architecture the most significant byte is stored at the lowest memory address. The author is partial to little endian machines; it just seems more natural to him although he knows people who swear by the opposite. Whichever endian is chosen, often the machine has instructions(s) for converting from one endian to the other. The author does not bother with endian conversion; it’s a feature that he probably wouldn’t use. Some implementations even allow the endian of the machine to be set by the user. This seems like overkill to the author. The endian of data is important because some file types depend on data being in little or big-endian format. Thor is a little-endian machine.

Endian

Thor2024 is a little-endian machine. The difference between big endian and little endian is in the ordering of bytes in memory. Bits are also numbered from lowest to highest for little endian and from highest to lowest for big endian.

Shown is an example of a 32-bit word in memory.

Little Endian:

Address	3	2	1	0
Byte	3	2	1	0

Big Endian:

Address	3	2	1	0
Byte	0	1	2	3

For Thor2024 the root opcode is in byte zero of the instruction and bytes are shown from right to left in increasing order. As the following table shows.

Address 3	Address 2	Address 1	Address 0
Byte 3	Byte 2	Byte 1	Byte 0
▼			
31 24	23 16	15 8	7 5 4 0
Constant ₈	Raspec ₈	Rtspec ₈	Sz ₃ Opcode ₅

Programming Model

Register File

Rn – General Purpose Registers

The register file contains 32 128-bit general purpose registers.

Register r0 is special in that it always reads as a zero.

The stack pointer, register 63, is banked with a separate stack pointer for each operation mode.

Registers may be loaded or stored individually or in groups of four 128-bit values.

Register ABI

Regno	ABI	Group Reg	ABI Usage
0	0	AG0	Always zero
1	A0		First argument / return value register
2	A1		Second argument / return value register
3	A2		Third argument register
4 to 7	T0 to T3	TG0	Temporary register, caller save
8 to 11	T4 to T7	TG1	Temporary register, caller save
12 to 15	S0 to S3	SG0	Saved register, register variables
16 to 19	S0 to S7	SG1	Saved register, register variables
20 to 23	A3 to A6	AG1	Argument register
24	S8	G6	Saved register, register variables
25	S9		Saved register, register variables
26	S10		Saved register, register variables
27	LC		Loop Counter
28	TP		Thread Pointer
29	GP		Global Pointer
30	FP		Frame Pointer
31	ASP		Application / User stack pointer
31	SSP		Supervisor Stack pointer
31	HSP		Hypervisor Stack pointer
31	MSP		Machine Stack pointer

Fn – Floating-Point Registers

The design includes a set of 32 128-bit floating point registers.

Regno	ABI	Group Reg	ABI Usage
0	0	FG0	Always zero
1	A0		First argument / return value register
2	A1		Second argument / return value register
3	A2		Third argument register
4 to 15	T0 to T11	FG1, FG2, FG3	Temporary register, caller save
16 to 27	S0 to S11	FG4, FG5, FG6	Saved register, register variables
28 to 31	A3 to A6	FG7	Argument Register

Pn - Predicate Registers

There are 16 128-bit predicate registers.

Predicate registers are used to mask off vector operations so that a vector instruction doesn't perform the operation on all elements of the vector.

Code Address Registers

Many architectures have registers dedicated to addressing code. Almost every modern architecture has a program counter or instruction pointer register to identify the location of instructions. Many architectures also have at least one link register or return address register holding the address of the next instruction after a subroutine call. There are also dedicated branch address registers in some architectures. These are all code addressing registers.

The original Thor lumped these registers together in a code address register array. For Thor2023 some of these registers are now part of the general register file.

It is possible to do an indirect method call using any register.

LRn – Link Registers

There are three registers in the Thor2024 architecture reserved for subroutine linkage. These registers are used to store the address after the calling instruction. They may be used to implement fast returns for several levels of subroutines or to used to call milli-code routines. The jump to subroutine, [JSR](#), and branch to subroutine, [BSR](#), instructions update a link register. The return from subroutine, [RTS](#), instruction is used to return to the next instruction.

PC – Program Counter

This register points to the currently executing instruction. The program counter increments as instructions are fetched, unless overridden by another flow control instruction. The program counter may be set to any wyde address. There is no alignment restriction. It is possible to write position independent code, PIC, using PC relative addressing.

LC - Loop Counter (reg 27)

The loop counter register is used in counted loops along the decrement and branch, [DBcc](#), and REP modifier instructions.

SR - Status Register (CSR 0x?004)

The processor status register holds bits controlling the overall operation of the processor, state that needs to be saved and restored across interrupts. The bits have individual bit set / clear capability using the CSRRS, CSRRC instructions. Only the user interrupt enable bit is available in user mode, other bits will read as zero.

Bit	Usage	
0	uie	User interrupt enable
1	sie	Supervisor interrupt enable

2	hie	Hypervisor interrupt enable
3	mie	Machine interrupt enable
4	die	Debug interrupt enable
5 to 7	ipl	Interrupt level
8	ssm	Single step mode
9	te	Trace enable
10 to 11	om	Operating mode
12 to 13	ps	Pointer size
14 to 15	~	reserved
16	mprv	memory privilege
17	~	reserved
18	dmi	Decimal mode for integers
19	dmf	Decimal mode for float
20 to 23	~	reserved
24 to 31	cpl	Current privilege level

CPL is the current privilege level the processor is operating at.

T indicates that trace mode is active.

OM processor operating mode.

PS: indicates the size of pointers in use. This may be one of 32, 64 or 128 bits.

AR: Address Range indicates the number of address bits in use. 0 = near or short (32-bit) addressing is in use. When short addressing is in use only the low order 32-bit are significant and stored or loaded to or from the stack.

IPL is the interrupt mask level

RT specifies the return type for an [RTI](#) instruction.

MPRV Memory Privilege, indicates to use previous operating mode for memory privileges

Decimal Mode

~~Setting the 'D' flag bit 5 in the SR register sets the processor in decimal operating mode. Arithmetic operations will use BCD numbers for both source and destination operands.~~

~~Decimal mode, 'D' flag bit 4, may also be applied to floating point which will use decimal floating point operations instead of binary.~~

Decimal mode is now handled on an instruction-by-instruction basis with bits in the instruction indicating when decimal mode is in use.

Vector Programming Model

Register File

Vn – SIMD Registers

The SIMD register file contains 32 512-bit registers.

Regno	ABI	ABI Usage
0		
1	VA0	First argument / return value
2	VA1	Second argument / return value
3	VA2	Third argument
4 to 15	VT0 to VT11	
16 to 27	VS0 to VS11	
28 to 31	VA3 to VA6	

Vector Related CSRs

VGM		Global mask register
VRM		Restart mask register
VERR		Error mask register
VRGSZ		Vector register size
VED		Vector element descriptor

The number of elements is limited to 128 as that is the width of a predicate register.

Vector Global Mask Register (VGM)

The global mask register contains predicate bits indicating which vector elements are active. Vector elements of the target are updated only when the corresponding global mask bit is set. The global mask register takes the place of the vector length register in other architectures. Normally the global mask contains a right aligned bitmask of all ones up to the number of elements to be processed.

Vector Restart Mask Register (VRM)

The restart mask register contains a bitmask indicating the vectors elements to be processed after a restart. The restart mask register is set to all ones at the end of a vector operation.

Vector Error Mask Register (VERR)

The vector error mask register contains a bit for each vector element indicating if an error occurred.

Vector Register Size (VRGSZ)

The vector register size register contains the length of a vector register in bytes. Only the low order eight bits of the register are implemented, other bits read as zero, and ignore writes.

Vector Element Description Register (VED)

This register contains bits describing an element of a vector.

127	6	5	3	2	0
	~	OT ₃	Size ₃		

Size ₃	Bits	Bytes
0	8	1
1	16	2
2	32	4
3	64	8
4	128	16
5	256	32
6	512	64
7		reserved

OT ₃	Operand Type
0	Integer
1	Float
2	Decimal
3	Posit
4	Char
5 to 7	reserved

Register-Register Format

Fmt ₃	Rb	Ra	Rt	Mask
000	scalar	scalar	scalar	No
001	scalar	scalar	scalar	Yes
010	scalar	vector	vector	No
011	scalar	vector	vector	Yes
100	vector	vector	vector	No
101	vector	vector	vector	Yes

Special Purpose Registers

SC - Stack Canary (GPR 53)

This special purpose register is available in the general register file as register 53. The stack canary register is used to alleviate issues resulting from buffer overflows on the stack. The canary register contains a random value which remains consistent throughout the run-time of a program. In the right conditions, the canary register is written to the stack during the function's prolog code. In the function's epilog code, the value of the canary on stack is checked to ensure it is correct, if not a check exception occurs.

[U/S/H/M]_IE (0x?004)

See status register.

This register contains interrupt enable bits. The register is present at all operating levels. Only enable bits at the current operating level or lower are visible and may be set or cleared. Other bits will read as zero and ignore writes. Only the lower four bits of this register are implemented. The bits have individual bit set / clear capability using the CSRRS, CSRRC instructions.

63		4	3	2	1	0
~			mie	hie	sie	uie

[U/S/H/M]_CAUSE (CSR- 0x?006)

This register contains a code indicating the cause of an exception or interrupt. The break handler will examine this code to determine what to do. Only the low order 12 bits are implemented. The high order bits read as zero and are not updateable.

U_REPBUF - (CSR – 0x008)

This register contains information needed for the REP instruction that must be saved and restored during context switches and interrupts. Note that the loop counter should also be saved.

127	112	121		48	47	44	43	42	40	39		8	7	6	0
Resv	pc				Resv2	V	ICnt	Limit			resv	Ins[15:9]			

Pc: (64 bits) the address of the instruction following the REP

V: REP valid bit, 1 only if a REP instruction is active

ICnt: the current instruction count, distance from REP instruction.

Limit: a 32-bit amount to compare the loop counter against.

Ins: bits 9 to 15 of the REP instruction which contains the instruction count of instruction included in the repeat and condition under which the repeat occurs.

[U/S/H/M]_SCRATCH – CSR 0x?041

This is a scratchpad register. Useful when processing exceptions. There is a separate scratch register for each operating mode.

S_PTBR (CSR 0x1003)

This register contains the base address of the page table, which must be a multiple of 16384. Also included in this register is table parameters depth and type. Register tag #152.

95	14	13 12	11 8	7 6	5 4	3	2 1	0
Page Table Address _{67..14}	~ ₂	Levels	AL ₂	~ ₂	S	~	Type	

Type: 0 = inverted page table, 1 = page table

S: 1=software managed TLB miss, 0 = hardware table walking

Levels are ignored for the inverted page table. For a normal page table gives the top entry level.

AL₂: TLB entry replacement algorithm, 0=fixed,1=LRU,2=random,3=reserved

S_ASID (CSR 0x101F)

This register contains the address space identifier (ASID) or memory map index (MMI). The ASID is used in this design to select (index into) a memory map in the paging tables. Only the low order twelve bits of the register are implemented.

S_KEYS (CSR 0x1020 to 0x1027)

These eight registers contain the collection of keys associated with the process for the memory lot system. Each key is twenty-four bits in size. All eight registers are searched in parallel for keys matching the one associated with the memory page. Keyed memory enhances the security and reliability of the system.

			23	0
1020			key0	
1021			key1	
...			...	
1027			key7	

M_CORENO (CSR 0x3001)

This register contains a number that is externally supplied on the coreno_i input bus to represent the hardware thread id or the core number. It should be non-zero.

M_TICK (CSR 0x3002)

This register contains a tick count of the number of clock cycles that have passed since the last reset. Note that this register should not be used for precise timing as the processor's clock frequency may vary for performance and power reasons. The TIME CSR may be used for wall-clock timing as it has its own timing source.

M_SEED (CSR 0x3003)

This register contains a random seed value based on an external entropy collector. The most significant bit of the state is a busy bit.

63	60	59		16	15	0
State ₄			~44		seed ₁₆	

State ₄ Bit	
0	dead
1	test
2	valid, the seed value is valid
3	Busy, the collector is busy collecting a new seed value

M_BADADDR (CSR 0x3007)

This register contains the address for a load / store operation that caused a memory management exception or a bus error. Note that the address of the instruction causing the exception is available in the EPC register.

M_BAD_INSTR (CSR 0x300B)

This register contains a copy of the exceptioned instruction.

M_SEMA (CSR 0x300C)

This register contains semaphores. The semaphores are shared between all cores in the MPU.

M_TVEC – CSR 0x3030 to 0x3034

These registers contain the address of the exception handling routine for a given operating level. TVEC[4] (0x3034) is used directly by hardware to form an address of the debug routine. The lower eight bits of TVEC[3] are not used. The lower bits of the exception address are determined from the operating level. TVEC[0] to TVEC[2] are used by the REX instruction.

A sync instruction should be used after modifying one of these registers to ensure the update is valid before continuing program execution.

Reg #	
0x3030	TVEC[0] – user mode

0x3031	TVEC[1] - supervisor mode
0x3032	TVEC[2] – hypervisor mode
0x3033	TVEC[3] – machine mode
0x3034	TVEC[4] - debug

M_SR_STACK (CSR 0x303C to CSR 0x303D)

This pair of registers contains a stack of the status register which is pushed during exception processing and popped on return from interrupt. There are only eight slots as that is the maximum nesting depth for interrupts.

	127	96	95	64	63	32	31	0
0x303C	SR3		SR2		SR1		SR0	
0x303D	SR7		SR6		SR5		SR4	

M_IOS – IO Select Register (CSR 0x3100)

The location of IO is determined by the contents of the IOS control register. The select is for a 1MB region. This address is a virtual address. The low order 16 bits of this register should be zero and are ignored.

63	16	15	0
Virtual Address _{67..20}		0 ₁₆	

M_EPC (CSR 0x3108 to 0x310F)

This set of registers contains the address stack for the program counter used in exception handling.

Reg #	Name
0x3108	EIP0
...	
0x310F	EIP7

AV – Application Vector Table Address

This register holds the address of the applications vector table. The vector table must be 16-byte aligned.

63	0
App Vector Table Address _{67..4}	

VB – Vector Base Register

The vector base register provides the location of the vector table. The vector table must be octa aligned. On reset the VBR is loaded with zero. There is a separate vector base register for each operating mode.

63	3	2	1	0
----	---	---	---	---

Vector Table Address _{63...3}	~	~
--	---	---

Operating Modes

The core operates in one of four basic modes: application/user mode, supervisor mode, hypervisor mode or machine mode. Machine mode is switched to when an interrupt or exception occurs, or when debugging is triggered. On power-up the core is running in machine mode. An RTI instruction must be executed to leave machine mode after power-up.

A subset of instructions is limited to machine mode.

Mode Bits	Mode
0	User / App
1	Supervisor
2	Hypervisor
3	Machine

Memory Management

Bank Swapping

About the simplest form of memory management is a single bank register that selects the active memory bank. This is the mechanism used on many early microcomputers. The bank register may be an eight bit I/O port supplying control over some number of upper address bits used to access memory.

The Page Map

The next simplest form of memory management is a single table map of virtual to physical addresses. The page map is often located in a high-speed dedicated memory. An example of a mapping table is the 74LS612 chip. It may map four address bits on the input side to twelve address bits on the output side. This allows a physical address range eight bits greater than the virtual address range. A more complicated page map is something like the MC6829 MMU. It may map 2kB pages in a 2MB physical address space for up to four different tasks.

Regions

In any processing system there are typically several different types of storage assigned to different physical address ranges. These include memory mapped I/O, MMIO, DRAM, ROM, configuration space, and possibly others. Thor2023 has a region table that supports up to eight separate regions.

The region table is a list of region entries. Each entry has a start address, an end address, an access type field, and a pointer to the PMT, page management table. To determine legal access types, the physical address is searched for in the region table, and the corresponding access type returned. The search takes place in parallel for all eight regions.

Once the region is identified the access rights for a particular page within the region can be found from the PMT corresponding to the region. Global access rights for the entire region are also specified in the region table. These rights are gated with value from the PMT and TLB to determine the final access rights.

PMA - Physical Memory Attributes Checker

Overview

The physical memory attributes checker is a hardware module that ensures that memory is being accessed correctly according to its physical attributes.

Physical memory attributes are stored in an eight-entry region table. Three bits in the PTE select an entry from this table. The operating mode of the CPU also determines which 32-bit set of attributes to apply for the memory region.

Most of the entries in the table are hard-coded and configured when the system is built. However, they may be modified at the address range \$F...F9F0xxx.

Physical memory attributes checking is applied in all operating modes.

The region table is accessible as a memory mapped IO, MMIO, device.

Region Table Description

Reg	Bits		
00	128	Pmt	associated PMT address
01	128	cta	Card table address
02	128	at	Four groups of 32-bit memory attributes, 1 group for each of user, supervisor, hypervisor and machine.
03	128	...	Not used
04 to 1F		...	7 more register sets

PMT Address

The PMT address specifies the location of the associated PMT.

CTA – Card Table Address

The card table address is used during the execution of the store pointer, STPTR instruction to locate the card table.

Attributes

Bitno												
0	X	may contain executable code

24-31	~	reserved		

Page Management Table - PMT

Overview

For the first translation of a virtual to physical address, after the physical page number is retrieved from the TLB, the region is determined, and the page management table is referenced to obtain the access rights to the page. PMT information is loaded into the TLB entry for the page translation. The PMT contains an assortment of information most of which is managed by software. Pieces of information include the key needed to access the page, the privilege level, and read-write-execute permissions for the page. The table is organized as rows of access rights table entries (PMTEs). There are as many PMTEs as there are pages of memory in the region.

For subsequent virtual to physical address translations PMT information is retrieved from the TLB.

As the page is accessed in the TLB, the TLB may update the PMT.

Location

The page management table is in main memory and may be accessed with ordinary load and store instructions. The PMT address is specified by the region table.

PMTE Description

There is a wide assortment of information that goes in the page management table. To accommodate all the information an entry size of 128-bits was chosen.

Page Management Table Entry

V	N	M	~9				C	E	AL ₂	~16							
ACL ₁₆									Share Count ₁₆								
Access Count ₃₂																	
PL ₈				Key ₂₄													

Access Control List

The ACL field is a reference to an associated access control list.

Share Count

The share count is the number of times the page has been shared to processes. A share count of zero means the page is free.

Access Count

This part uses the term 'access count' to refer to the number of times a page is accessed. This is usually called the reference count, but that phrase is confusing because reference counting may

also refer to share counts. So, the phrase ‘reference count’ is avoided. Some texts use the term reference count to refer to the share count. Reference counting is used in many places in software and refers to the number of times something is referenced.

Every time the page of memory is accessed, the access count of the page is incremented. Periodically the access count is aged by shifting it to the right one bit.

The access count may be used by software to help manage the presence of pages of memory.

Key

The access key is a 24-bit value associated with the page and present in the key ring of processes. The keyset is maintained in the keys CSRs. The key size of 20 bits is a minimum size recommended for security purposes. To obtain access to the page it is necessary for the process to have a matching key OR if the key to match is set to zero in the PMTE then a key is not needed to access the page.

Privilege Level

The current privilege level is compared with the privilege level of the page, and if access is not appropriate then a privilege violation occurs. For data access, the current privilege level must be at least equal to the privilege level of the page. If the page privilege level is zero anybody can access the page.

N

indicates a conforming page of executable code. Conforming pages may execute at the current privilege level. In which case the PL field is ignored.

M

indicates if the page was modified, written to, since the last time the M bit was cleared. Hardware sets this bit during a write cycle.

E

indicates if the page is encrypted.

AL

indicates the compression algorithm used.

C

The C indicator bit indicates if the page is compressed.

Page Tables

Intro

Page tables are part of the memory management system used to map virtual addresses to real physical addresses. There are several types of page tables. Hierarchical page tables are probably the most common. Almost all page tables map only the upper bits of a virtual address, called a page. The lower bits of the virtual address are passed through without being altered. The page size is often 4kB, which means the low-order 12-bits of a virtual address will be mapped to the same 12-bits for the physical address.

Hierarchical Page Tables

Hierarchical page tables organize page tables in a multi-level hierarchy. They can map the entire virtual address range but often only a subrange of the full virtual address space is mapped. This can be determined on an application basis. At the topmost level, a register points to a page directory, that page directory points to a page directory at a lower level until finally a page directory points to a page containing page table entries. To map an entire 64-bit virtual address range, approximately five levels of tables are required.

Paged MMU Mapping

Inverted Page Tables

An inverted page table is a table used to store address translations for memory management. The idea behind an inverted page table is that there are a fixed number of pages of memory no matter how it is mapped. It should not be necessary to provide for a map of every possible address, which is what the hierarchical table does, only addresses that correspond to real pages of memory need be mapped. Each page of memory can be allocated only once. It is either allocated or it is

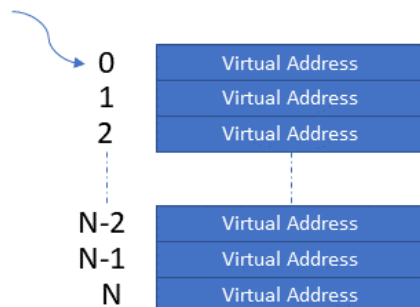

not. Compared to a non-inverted paged memory management system where tables are used to map potentially the entire address space an inverted page table uses less memory. There is typically only a single inverted page table supporting all applications in the system. This is a different approach than a non-inverted page table which may provide separate page tables for each process.

The Simple Inverted Page Table

The simplest inverted page table contains only a record of the virtual address mapped to the page, and the index into the table is used as the physical page number. There are only as many entries in the inverted page table as there are physical pages of memory. A translation can be made by scanning the table for a matching virtual address, then reading off the value of the table index. The attraction of an inverted page table is its small size compared to the typical hierarchical page table. Unfortunately, the simplest inverted page table is not practical when there are thousands or millions of pages of memory. It simply takes too long to scan the table. The alternative solution to scanning the table is to hash the virtual address to get a table index directly.

Inverted Page Table

Entry number identifies physical page number

Hashed Page Tables

Hashed Table Access

Hashes are great for providing an index value immediately. The issue with hash functions is that they are just a hash. It is possible that two different virtual address will hash to the same value. What is then needed is a way to deal with these hash collisions. There are a couple of different methods of dealing with collisions. One is to use a chain of links. The chain has each link in the chain pointing the to next page table entry to use in the event of a collision. The hash page table is slightly more complicated then as it needs to store links for hash chains. The second method is to use open addressing. Open addressing calculates the next page table entry to use in the event of a collision. The calculation may be linear, quadratic or some other function dreamed up. A linear probe simply chooses the next page table entry in succession from the previous one if no match occurred. Quadratic probing calculates the next page table entry to use based on squaring the count of misses.

Clustered Hash Tables

A clustered hash table works in the same manner as a hashed page table except that the hash is used to access a cluster of entries rather than a single entry. Hashed values may map to the same cluster which can store multiple translations. Once the cluster is identified, all the entries are searched in parallel for the correct one. A clustered hash table may be faster than a simple hash table as it makes use of parallel searches. Often accessing memory returns a cache line regardless of whether a single byte or the whole cached line is referenced. By using a cache line to store a cluster of entries it can turn what might be multiple memory accesses into a single access. For example, an ordinary hash table with open addressing may take up to 10 memory accesses to find the correct translation. With a clustered table that turns into 1.25 memory accesses on average.

Shared Memory

Another memory management issue to deal with is shared memory. Sometimes applications share memory with other apps for communication purposes, and to conserve memory space where there are common elements. The same shared library may be used by many apps running in the system. With a hierarchical paged memory management system, it is easy to share memory, just modify the page table entry to point to the same physical memory as is used by another process. With an inverted page table having only a single entry for each physical page is not sufficient to support shared memory. There needs to be multiple page table entries available for some physical pages but not others because multiple virtual addresses might map to the same physical address. One solution would be to have multiple buckets to store virtual addresses in for each physical address. However, this would waste a lot of memory because much of the time only a single mapped address is needed. There must be a better solution. Rather than reading off the table index as the physical page number, the association of the virtual and physical address can be stored. Since we now need to record the physical address multiple times the simple mechanism of using the table index as the physical page number cannot be used. Instead, the physical page number needs to be stored in the table in addition to the virtual page number.

That means a table larger than the minimum is required. A minimally sized table would contain only one entry for each physical page of memory. So, to allow for shared memory the size of the table is doubled. This smells like a system configuration parameter.

Specifics: Thor2023 Page Tables

Thor2023 Hash Page Table Setup

Hash Page Table Entries - HPTE

We have determined that a page table entry needs to store both the physical page number and the virtual page number for the translations. To keep things simple, the page table stores only the information needed to perform an address translation. Other bits of information are stored in a secondary table called the page management table, PMT. The author did a significant amount of juggling around the sizes of various fields, mainly the size of the physical and virtual page numbers. Finally, the author decided on a 192-bit HPTE format.

V	LVL/BC ₅	RGN ₃	M	A	T	S	G	SW ₂	CACHE ₄	MRWX ₃	HRWX ₃	SRWX ₃	URWX ₃

PPN _{63..32}													
VPN _{37.. 6}													
VPN _{69.. 38}													
~4		ASID _{11..0}						~2		VPN _{83.. 70}			

Fields Description

V	1	translation Valid
G	1	global translation
RGN	3	region
PPN	64	Physical page number
VPN	84	Virtual page number
RWX	3	readable, writeable, executable
ASID	12	address space identifier
LVL/BC	5	bounce count
M	1	modified
A	1	accessed
T	1	PTE type (not used)
S	1	Shared page indicator
SW	3	OS usage

The page table does not include everything needed to manage pages of memory. There is additional information such as share counts and privilege levels to take care of, but this information is better managed in a separate table.

Small Hash Page Table Entries - SHPTE

The small HPTE is used for the test system which contains only 512MB of physical RAM to conserve hardware resources. The SHPTE is 96-bits in size.

VPN _{5..0}		PPN _{25..0}											
ASID _{11..0}							VPN _{25.. 6}						

Page Table Groups – PTG

We want the search for translations to be fast. That means being able to search in parallel. So, PTEs are stored in groups that are searched in parallel for translations. This is sometimes referred to as a clustered table approach. Access to the group should be as fast as possible. There are also hardware limits to how many entries can be searched at once while retaining a high clock rate. So, the convenient size of 1024 bits was chosen as the amount of memory to fetch.

A page table group then contains ten SHPTE page-table entries or five HPTE entries. All entries in the group are searched in parallel for a match. Note that the entries are searched as the PTG is

loaded, so that the PTG group load may be aborted early if a matching PTE is found before the load is finished.

Size of Page Table

There are several conflicting elements to deal with, with regards to the size of the page table. Ideally, the hash page table is small enough to fit into the block RAM resources available in the FPGA. It may be practical to store the hash page table in block RAM as there would be only a single table for all apps in the system. This probably would not be practical for a hierarchical table.

About 1/3 of the block RAMs available are dedicated to MMU use. At the same time a multiple of the number of physical pages of memory should be supported to support page sharing and swapping pages to secondary storage. To support swapping pages, double the number of physical entries were chosen. To support page sharing, double that number again. Therefore, a minimum size of a page table would contain at least four times the number of physical pages for entries. By setting the size of the page table instead of the size of pages, it can be worked backwards how many pages of memory can be supported.

For a system using 512k block RAM to store PTEs. $512k / 96 = 5,461$ entries. $5,461 / 4 = 1,365$ physical pages. Since the RAM size is 512MB, each page would be $512MB / 1,365 = 393kB$. Rounding up, 512kB. Since half the pages may be in secondary storage, 1GB of address range is available. A 512kB page is probably too large to be useful, so either more block RAM is required, or the table could be place in main memory.

Since there are 5,461 entries in the table and they are grouped into groups of ten, there are 546 PTGs. To get to a page table group fast a hash function is needed then that returns a 10-bit number.

Hash Function

The hash function needs to reduce the size of a virtual address down to a 11-bit number. The asid should be considered part of the virtual address. Including the asid an address is 76 bits. The first thing to do is to throw away the lowest fourteen bits as they pass through the MMU unaltered. We now have 62-bits to deal with. We can probably throw away some high order bits too, as a process is not likely to use the full 64-bit address range.

The hash function chosen uses the asid combined with virtual address bits 18 to 28 and bits 29 to 39. This should space out the PTEs according to the asid. Address bits 16 and 17 select one of four address ranges. the PTG supports ten PTEs. The translations where address bits 16 and 17 are involved are likely consecutive pages that would show up in the same PTG. The hash is the asid exclusively or'd with address bits 18 to 28 exclusively or'd with address bits 29 to 39.

Collision Handling

Quadratic probing of the page table is used when a collision occurs. The next PTG to search is calculated as the hash plus the square of the miss count. On the first miss the PTG at the hash plus one is searched. Next the PTG at the hash plus four is searched. After that the PTG at the hash plus nine is searched, and so on.

Finding a Match

Once the PTG to be searched is located using the hash function, which PTE to use needs to be sorted out. The match operation must include both the virtual address bits and the asid, address space identifier, as part of the test for a match. It is possible that the same virtual address is used by two or more different address spaces, which is why it needs to be in the match.

Locality of Reference

The page table group may be cached in the system read cache for performance. It is likely that the same PTG group will be used multiple times due to the locality of reference exhibited by running software.

Access Rights

To avoid duplication of data the access rights are stored in another table called the PMT for access rights table. The first time a translation is loaded the access rights are looked-up from the PMT. A bit is set in the TLB entry indicating that the access rights are valid. On subsequent translations the access rights are not looked up, but instead they are read from values cached in the TLB.

Thor2023 Hierarchical Page Table Setup

Page Table Entries - PTE

For hierarchical tables the structure is like that of hashed page tables except that there is no need to store the virtual address. We know the virtual address because it is what is being translated and there is no chance of collisions unlike the hash table. The structure is 96 bits in size. This allows 1024 PTEs to fit into an 16kB page. ¼ of the 16kB page is not used. Note the size of pages in the table is a configuration parameter used to build the system.

There are two types of page table entries. The first type, T=0, is a pointer to a page of memory, the second type, T=1, is an entry that points to lower-level page tables. PTE's that point to lower-level page tables are sometimes called page table pointers, PTPs.

Page Table Entry Format – PTE

V	LVL/BC ₅	RGN ₃	M	A	T	S	G	SW ₂	CACHE ₄	MRWX ₃	HRWX ₃	SRWX ₃	URWX ₃
PPN _{31..0}													
PPN _{63..32}													

Small Page Table Entry Format – SPTE

The small PTE format is used when the physical address space is less than 46-bits in size. The small PTE occupies only 64-bits. 2048 SPTEs will fit into an 16kB page.

V	LVL/BC ₅	RGN ₃	M	A	T	S	G	SW ₂	CACHE ₄	MRWX ₃	HRWX ₃	SRWX ₃	URWX ₃
PPN _{31..0}													

Field	Size	Purpose
PPN	64	Physical page number
URWX	3	User read-write-execute override
SRWX	3	Supervisor read-write-execute override
HRWX	3	Hypervisor read-write-execute override
MRWX	3	Machine read-write-execute override
CACHE	4	Cache-ability bits
A	1	1=accessed/used
M	1	1=modified
V	1	1 if entry is valid, otherwise 0
S	1	1=shared page
G	1	1=global, ignore ASID
T	1	0=page pointer, 1= table pointer
RGN	3	Region table index
LVL/BC	5	the page table level of the entry pointed to

Super Pages

The hierarchical page table allows “super pages” to be defined. These pages bypass lower levels of page tables by using an entry at a high level to represent a block containing many pages.

Normally a PTE with LVL=0 is a pointer to an 16kB memory page. However, super-pages may be defined by specifying a page pointer with a LVL greater than zero. For instance, if T=0 and LVL=1 then the page pointed to is a super-page within an 16MB block of contiguous memory.

T=0, LVL=	Page Size
0	16 kB page
1	16 MB page
2	16 GB page
3	16 TB page
4	16 EB page
5	
6	
7	reserved

A super page pointer contains both a pointer to the block of pages and a super page length field. The length field is provided to restrict memory access to an address range between the super page pointer and the super page pointer plus the number of pages specified in the length. A typical use

would be to point to the system ROM which may be several megabytes and yet shorter than the maximum size of the super page.

For example, a system ROM is located 512 MB before the end of physical memory. The ROM is only 1MB in size. So, it is desired to setup a super page pointer to the ROM and restrict access to a single megabyte. The PTE for this would look like:

V	1 ₅	RGN ₃	M	A	0	S	G	SW ₂	~ ₄	MRWX ₃	HRWX ₃	SRWX ₃	URWX ₃
PPN=0x3FFFE0 ₂₂										NPG=0x03F ₁₀			
PPN=0xFFFFFFFF _{63..32}													

The PTE would be pointed to by a LVL=1 pointer resulting in a 16MB super-page size. 512MB is 32 pages before the end of memory, reflected in the value 0x3FFFE0₂₂ for the PPN above.

There are 64 x 16kB pages in 1MB so the length field, NPG, is set to 0x03F₁₀.

PTE Format for 16MB page

PPN _{31..10}										NPG ₁₀			
PPN _{63..32}													

PTE Format for 16GB page

V	2 ₅	RGN ₃	M	A	0	S	G	SW ₂	~ ₄	MRWX ₃	HRWX ₃	SRWX ₃	URWX ₃
PPN _{31..20}					NPG ₂₀								
PPN _{63..32}													

TLB – Translation Lookaside Buffer

Overview

A simple page map is limited in the translations it can perform because of its size. The solution to allowing more memory to be mapped is to use main memory to store the translations tables.

However, if every memory access required two or three additional accesses to map the address to a final target access, memory access would be quite slow, slowed down by a factor of two or three, possibly more. To improve performance, the memory mapping translations are stored in another unit called the TLB standing for Translation Lookaside Buffer. This is sometimes also called an address translation cache ATC. The TLB offers a means of address virtualization and memory protection. A TLB works by caching address mappings between a real physical address and a virtual address used by software. The TLB deals with memory organized as pages. Typically, software manages a paging table whose entries are loaded into the TLB as translations are required.

The TLB is a cache specialized for address translations. Thor2023's TLB is quite large being six-way associative with 1024 entries per way. This choice of size was based on the minimum number of block RAMs that could be used to implement the TLB. On a TLB miss the page table is searched for a translation and if found the translation is stored in one of the ways of the TLB. The way selected is determined either randomly or in a least-recently-used fashion as one of the first four ways. The last way may not be updated automatically by a page table search, it must be updated by software.

Size / Organization

The TLB has 1024 entries per set. The size was chosen as it is the size of one block ram for 32-bit data in the FPGA. This is quite a large TLB. Many systems use smaller TLBs. Typically, systems vary between 64 and 1024 entries. There is not really a need for such a large one, however it is available.

The TLB is organized as a six-way set associative cache. The last way may only be updated by software. The last way allows translations to be stored that will not be overwritten. The first four ways may use hardware LRU replacement in addition to fixed or random replacement.

Way	Page size
0	16kB pages
1	16kB pages
2	16kB pages
3	16kB pages
4	16MB pages
5	16kB pages

Note that 16MB pages do not need multiple ways as there are sufficient TLB entries to allow distinct entries for each 16MB page if the virtual address space is 34-bits or less.

TLB Entries - TLBE

Closely related to page table entries are translation look-aside buffer, TLB, entries. TLB entries have additional fields to match against the virtual address. The count field is used to invalidate the entire TLB. Note that the least significant 10-bits of the virtual address are not stored as these bits are used as an index for the TLB entry.

Count ₆	LRU ₃
--------------------	------------------

V	LVL/BC ₅	RGN ₃	M	A	T	S	G	SW ₂	CACHE ₄	MRWX ₃	HRWX ₃	SRWX ₃	URWX ₃
PPN _{31..0}													
PPN _{63..32}													

VPN _{41..10}													
VPN _{73..42}													
~4		ASID _{11..0}						~5		VPN _{83..73}			

Small TLB Entries - TLBE

The small TLB is used for the test system which contains only 512MB of physical RAM to conserve hardware resources. The address ranges are more limited, 40-bits for the physical address and 70-bits for the virtual address.

Count ₆	LRU ₃
--------------------	------------------

VPN _{41..10}													
~4		ASID _{11..0}						PS	~	VPN _{55..42}			

What is Translated?

The TLB processes addresses including both instruction and data addresses for all modes of operation. It is known as a *unified* TLB.

Page Size

Because the TLB caches address translations it can get away with a much smaller page size than the page map can for a larger memory system. 4kB is a common size for many systems. There are some indications in contemporary documentation that a larger page size would be better. In this case the TLB uses 16kB. For a 512MB system (the size of the memory in the test system) there are 32768 16kB pages.

Ways

The first four ways in the TLB are reserved for 16kB page translations. The next way, 4 is reserved for 16MB page translations. The last way is reserved for fixed translations of 16kB pages.

Management

The TLB unit may be updated by either software or hardware. This is selected in the page table base register. If software miss handling is selected when a translation miss occurs, an exception is generated to allow software to update the TLB. It is left up to software to decide how to update the TLB. There may be a set of hierarchical page tables in memory, or there could be a hash table used to store translations.

Accessing the TLB

A TLB entry contains too much information to be updated with a single register write. Since the information must also be updated atomically to ensure correct operation, the TLB update occurs in an indirect fashion. First holding registers are loaded with the desired values, then all the holding registers are written to the TLB in a single atomic cycle. The TLB is addressed in the physical memory space in the address range \$F...FE000xx. There are eight buckets which must be filled with TLB info using store instructions. Then address \$F...FE0007E is written to causing the TLB to be updated.

The low order bits of the bucket six determine which way to update in the TLB if the algorithm is a fixed way algorithm. Otherwise, if LRU is selected the LRU entry will be updated, otherwise a way to update will be selected randomly. The data is octa-byte aligned.

add	sp,sp,32	
rts		

TLB Entry Replacement Policies

The TLB supports three algorithms for replacement of entries with new entries on a TLB miss. These are fixed replacement (0), least recently used replacement (1) and random replacement (2). The replacement method is stored in the AL₂ bits of the page table base register.

For fixed replacement, the way to update must be specified by a software instruction. Least recently used replacement, LRU, selects the least recently used address translation to be overwritten. Random replacement chooses a way to replace at random.

Flushing the TLB

The TLB maintains the address space (ASID) associated with a virtual address. This allows the TLB translations to be used without having to flush old translations from the TLB during a task switch.

Reset

On a reset the TLB is preloaded with translations that allow access to the system ROM.

Global Bit

In addition to the ASID the TLB entries contain a bit that indicates that the translation is a global translation and should be present in every address space.

Card Table

Overview

Also present in the memory system is the Card table. The card table is a telescopic memory which reflects with increasing detail where in the memory system a pointer write has occurred. This is for the benefit of garbage collection systems. Card table is updated using a write barrier when a pointer value is stored to memory, or it may be updated automatically using the STPTR instruction.

Organization

At the lowest level memory is divided into 256-byte card memory pages. Each card has a single byte recording whether a pointer store has taken place in the corresponding memory area. To cover a 512MB memory system 2MB card memory is required at the outermost layer. A byte is used rather than a bit to allow byte store operations to update the table directly without having to resort to multiple instructions to perform a bit-field update.

To improve the performance of scanning a hardware card table, HCT, is present which divides memory at an upper level into 8192-byte pages. The hardware card table indicates if a pointer store operation has taken place in one of the 8192-byte pages. It is then necessary to scan only cards representing the 8192-byte page rather than having to scan the entire 2MB card table. Note that this memory is organized as 2048 32-bit words. Allowing 32-bits at a time to be tested.

To further improve performance a master card table, MCT, is present which divides memory at the uppermost layer into 16-MB pages.

Layer	Resolving Power	
0	2 MB	256B pages
1	64k bits	8kB pages
2	32 bits	16 MB pages

There is only a single card memory in the system, used by all tasks.

Location

Card memory must be based at physical address zero, extending up to the amount of card memory required. This is so that the address calculation of the memory update may be done with a simple right-shift operation.

Operation

As a program progresses it writes pointer values to memory using the write barrier. Storing a pointer triggers an update to all the layers of card memory corresponding to the main memory location written. A bit or byte is set in each layer of the card memory system corresponding to the memory location of the pointer store.

The garbage collection system can very quickly determine where pointer stores have occurred and skip over memory that has not been modified.

Sample Write Barrier

```
; Milli-code routine for garbage collect write barrier.  
; This sequence is short enough to be used in-line.  
; Three level card memory.  
; a2 is a register pointing to the card table.  
; STPTR will cause an update of the master card table, and hardware card table.  
;
```

GCWriteBarrier:

STPTR	a0,[a1]	; store the pointer value to memory at a1
LSR	t0,a1,#8	; compute card address
STB	r0,[a2+t0]	; clear byte in card memory

Arithmetic Operations

Representations

long

int

short

char

byte

decimal

Decimal integers use densely packed decimal format which provide 38 digits of precision.

Arithmetic Operations

Arithmetic operations include addition, subtraction, multiplication and division. These are available with the ADD, SUB, CMP, MUL, and DIV instructions. There are several variations of the instructions to deal with signed and unsigned values. The format of the typical immediate mode instruction is shown below:

ADD Rt,Ra,Imm₁₅

Instruction Format: RI

31	17	16	12	11	7	6	0
Immediate _{14..0}				Ra ₅		Rt ₅	
						4 ₇	

Immediate instructions may have the constant overridden via the use of postfix immediates. In fact, almost all instructions can work with postfix immediates.

ADD Rt,Ra,Imm₂₄

31	17	16	12	11	7	6	0
~ ₁₄		Ra ₅		Rt ₅		4 ₇	
Immediate _{23..0}						1	127 ₇

There may seem to be significant wasted space in the instruction when an instruction postfix is used. However, the use of a postfix is the rare case which occurs when a fifteen-bit immediate value is not sufficient. Having the postfix begin with bit 0 to 23 encoded is to allow for instructions that do not have space for an immediate field in the instruction. The postfix usage is kept consistent between all instructions to make decoding easier to handle and smaller resource wise.

Note that all arithmetic instructions can use an immediate value via a postfix immediate. Not all arithmetic instructions support a fifteen-bit immediate field. Instead, when a postfix is used it will override the value coming from register Rb. The following instruction ignores the Rb register value and multiplies by a postfix immediate.

MULSU Rt, Ra, Rb

39	34	33	32	31	30	29	28	23	22	21	16	15	14	9	8	7	5	4	0
6 ₆	1	Vc	1	Vb	Sb	Rb ₆	Sa	Ra ₆	St	Rt ₆	V	Sz ₃	2 ₅						
Immediate _{31..0}												0 ₃	31 ₅						

There are both signed and unsigned versions of the arithmetic operations. However, note there is no signed or unsigned compare operation as a single compare instruction produces results for both signed and unsigned comparisons. Signed and unsigned ADD and SUB currently work the same way. Two separate versions have been reserved to support the overflow exception in the future.

ABS – Absolute Value

Description:

This instruction computes the absolute value of the contents of the source operand and places the result in Rt.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	3 ₅	Ra ₅	Rt ₅	1h ₇

Operation:

If $Ra < 0$
 $Rt = -Ra$
else
 $Rt = Ra$

Execution Units: Integer ALU #0

Clock Cycles: 1

Exceptions: none

Notes:

ADD - Register-Register

Description:

Add two registers and place the sum in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	4 ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇	

Operation: R2

$$Rt = Ra + Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

ADDI - Add Immediate

Description:

Add a register and immediate value and place the sum in the target register. The immediate is sign extended to the machine width.

Instruction Format: RIQ

15	12	11	7	6	0
Imm _{3..0}	Rt ₅	16 ₇			

Instruction Format: RI

31	30	29	27	26	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{9..0}		Ra ₅	Rt ₅					4 ₇	

Clock Cycles: 1

Execution Units: All ALU's

Operation:

$$Rt = Ra + \text{immediate}$$

Exceptions:

Notes:

ADDIPC - Add Immediate to Program Counter

Description:

Add the program counter and immediate value and place the sum in the target register. The immediate is sign extended to the machine width. This instruction is used to generate relative addresses.

Instruction Format: ADDIPC

31 30	29 27	26	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{14..0}	Rt ₅	96 ₇			

Clock Cycles: 1

Execution Units: All ALU's

Operation:

$$Rt = Ra + \text{immediate}$$

Exceptions:

Notes:

AND – Bitwise And

Description:

Bitwise and two registers and place the result in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	Op ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇					

Operation: R2

$$Rt = Ra \& Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

ANDI - Add Immediate

Description:

Add a register and immediate value and place the sum in the target register. The immediate is sign extended to the machine width.

Instruction Format: RI

31 30	29 27	26	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{9..0}	Ra ₅	Rt ₅	8 ₇				

Clock Cycles: 1

Execution Units: All ALU's

Operation:

$$Rt = Ra + \text{immediate}$$

Exceptions:

Notes:

BMAP – Byte Map

Description:

First the target register is cleared, then bytes are mapped from the 16-byte source Ra into bytes in the target register. This instruction may be used to permute the bytes in register Ra and store the result in Rt. This instruction may also pack bytes, wydes or tetras. The map is determined by the low order 64-bits of register Rb or a 64-bit immediate constant. Bytes which are not mapped will end up as zero in the target register. Each nybble of the 64-bit value indicates the target byte in the target register.

Instruction Format: R2

BMAP Rt, Ra, Rb

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	3 ₄	Rb ₅	Ra ₅	Rt ₅	3h ₇

BMAP Rt, Ra, Imm64

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	3 ₄	0 ₅	Ra ₅	Rt ₅	3h ₇

79	8 7 6 0
~ ₈	Immediate ₆₄ 1 126 ₇

Operation:

Vector Operation

Execution Units: First Integer ALU

Exceptions: none

Notes:

BMM – Bit Matrix Multiply

BMM Rt, Ra, Rb

Description:

The BMM instruction treats the bits of register Ra and register Rb as an 8x8 matrix and performs a bit matrix multiply of the two registers and stores the result in the target register. An alternate mnemonic for this instruction is MOR.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	2 ₄	Rb ₅	Ra ₅	Rt ₅	3h ₇

Operation:

for I = 0 to 7

for j = 0 to 7

$Rt.bit[i][j] = (Ra[i][0] \& Rb[0][j]) \mid (Ra[i][1] \& Rb[1][j]) \mid \dots \mid (Ra[i][7] \& Rb[7][j])$

Clock Cycles: 1

Execution Units: First Integer ALU

Exceptions: none

Notes:

The bits are numbered with bit 63 of a register representing I,j = 0,0 and bit 0 of the register representing I,j = 7,7.

CHARNDX – Character Index

Description:

This instruction searches Ra, which is treated as an array of characters, for a character value specified by Rb and places the index of the character into the target register Rt. If the character is not found -1 is placed in the target register. A common use would be to search for a null character. The index result may vary from -1 to +15. The index of the first found byte is returned (closest to zero). The result is -1 if the character could not be found.

Supported Operand Sizes: .b, .w, .t

Instruction Format: R2 (byte)

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	5 ₄	Rb ₅	Ra ₅	Rt ₅	3h ₇

Instruction Format: R2 (wyde)

31 29	28 25	26 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	6 ₄	Rb ₅	Ra ₅	Rt ₅	3h ₇

Instruction Format: R2 (tetra)

31 29	28 25	26 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	7 ₄	Rb ₅	Ra ₅	Rt ₅	3h ₇

Operation:

Rt = Index of (Rb in Ra)

Execution Units: All Integer ALU's

Exceptions: none

Notes:

CLMUL – Carry-less Multiply

Description:

Compute the low order product bits of a carry-less multiply.

Instruction Formats:

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	6 ₄	Rb ₅	Ra ₅	Rt ₅	19 ₇

Exceptions: none

Execution Units: First Integer ALU

Operations

$$Rt = Ra * Rb$$

Vector Operation

for $x = 0$ to $VL - 1$

if $(Vm[x]) \quad Vt[x] = Va[x] * Vb[x]$

else if $(z) \quad Vt[x] = 0$

else $Vt[x] = Vt[x]$

Exceptions: none

CMP - Comparison

Description:

Compare two source operands and place the result in the target register. The result is a bit vector identifying the relationship between the two source operands as signed and unsigned integers.

Operation:

$R_t = R_a ? R_b$ or $R_t = R_a ? Imm$ or $R_t = Imm ? R_a$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

CNTLZ – Count Leading Zeros

Description:

This instruction counts the number of consecutive zero bits beginning at the most significant bit towards the least significant bit.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	0 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

Execution Units: Integer ALU #0

Clock Cycles: 1

Exceptions: none

Notes:

CNTLO – Count Leading Ones

Description:

This instruction counts the number of consecutive one bits beginning at the most significant bit towards the least significant bit.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	l ₅	Ra ₅	Rt ₅	lh ₇

Operation:

Execution Units: Integer ALU #0

Clock Cycles: 1

Exceptions: none

Notes:

CNTPOP – Count Population

Description:

This instruction counts the number of bits set in a register.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	2 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

Execution Units: Integer ALU #0

Clock Cycles: 1

Exceptions: none

Notes:

DIV – Signed Division

Description:

Divide source dividend operand by divisor operand and place the quotient in the target register.
All registers are integer registers. Arithmetic is signed twos-complement values.

Operation:

$$Rt = Ra / Rb$$

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	l ₄	Rb ₅	Ra ₅	Rt ₅	22 ₇

Execution Units: All Integer ALU's

Exceptions: none

Notes:

DIVI – Signed Immediate Division

Description:

Divide source dividend operand by divisor operand and place the quotient in the target register.
All registers are integer registers. Arithmetic is signed twos-complement values.

Operation:

$Rt = Ra / Rb$ or $Rt = Ra / Imm$

Instruction Format: RI

31 30	29 27	26	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{9..0}	Ra ₅	Rt ₅	13 ₇				

Execution Units: All Integer ALU's

Exceptions: none

Notes:

ENOR – Bitwise Exclusive Nor

Description:

Bitwise exclusively nor two registers and place the result in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	10 ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇	

Operation: R2

$$Rt = Ra \wedge Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

EOR – Bitwise Exclusive Or

Description:

Bitwise exclusively or two registers and place the result in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	2 ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇	

Operation: R2

$$Rt = Ra \wedge Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

EORI – Exclusive Or Immediate

Description:

Exclusive Or a register and immediate value and place the sum in the target register. The immediate is sign extended to the machine width.

Instruction Format: RI

31 30	29 27	26	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{9,0}	Ra ₅	Rt ₅	10 ₇				

Clock Cycles: 1

Execution Units: All ALU's

Operation:

$$Rt = Ra + \text{immediate}$$

Exceptions:

Notes:

MAX – Maximum Value

Description:

Determines the maximum of two values in registers Ra and Rb and places the result in the target register Rt.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	1 ₄	Rb ₅	Ra ₅	Rt ₅	3h ₇

Execution Units: ALU #0 only

Operation:

IF (Ra > Rb)
 Rt = Ra
else
 Rt = Rb

MIN – Minimum Value

Description:

Determines the minimum of two values in registers Ra and Rb and places the result in the target register Rt.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	0 ₄	Rb ₅	Ra ₅	Rt ₅	3h ₇

Clock Cycles: 1

Execution Units: ALU #0 only

Operation:

Operation:

IF (Ra < Rb)
 Rt = Ra
else
 Rt = Rb

MFLK – Move from Link Register

Description:

This instruction moves a link register to a general-purpose register.

Instruction Format: MFLK

15	14	12	11	7	6	0
1	L ₃	Rt ₅	119 ₇			

L ₃	Reg	
0	LR0	
1	LR1	
2	LR2	
3	LR3	
4 to 6		
7	VL	Vector length register

MTLK – Move to Link Register

Description:

This instruction moves a general-purpose register to a link register.

Instruction Format: MFLK

15	14	12	11	7	6	0
0	L ₃	Rs ₅	119 ₇			

MOVSXB – Move, Sign Extend Byte

Description:

A byte is extracted from the source operand, sign extended, and the result placed in the target register.

Operation:

Instruction Format: BITFLD

MOVSXB Rt, Ra

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	5 ₃	1	1	0 ₂	~ ₄	7 ₇		0 ₇		Ra ₅		Rt ₅		10 ₄	7

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MOVSXT – Move, Sign Extend Tetra

Description:

A tetra is extracted from the source operand, sign extended, and the result placed in the target register.

Operation:

Instruction Format: BITFLD

MOVSXW Rt, Ra

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	5 ₃	1	1	0 ₂	~ ₄	31 ₇		0 ₇		Ra ₅		Rt ₅		10 ₄	7

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MOVSXW – Move, Sign Extend Wyde

Description:

A wyde is extracted from the source operand, sign extended, and the result placed in the target register.

Operation:

Instruction Format: BITFLD

MOVSXW Rt, Ra

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	5 ₃	1	1	0 ₂	~ ₄	15 ₇		0 ₇		Ra ₅		Rt ₅		10 ₄	7

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MUL – Multiply Register-Register

Description:

Multiply two registers and place the product in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers. Values are treated as signed integers.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	Op ₄	Rb ₅	Ra ₅	Rt ₅	22 ₇	

Operation: R2

$$Rt = Ra * Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MULH – Multiply High

Description:

Compute the high order product of two values. Both operands must be in registers. Both the operands are treated as signed values, the result is a signed result.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	8 ₄	Rb ₅	Ra ₅	Rt ₅	22 ₇

Exceptions: none

Execution Units: ALU

Operation

$$Rt = Ra * Rb$$

Vector Operation

for $x = 0$ to $VL - 1$

if $(Pr[x] \& VGM[x])$ $Vt[x] = Va[x] * Vb[x]$

else $Vt[x] = Vt[x]$

Exceptions: none

MULI - Multiply Immediate

Description:

Multiply a register and immediate value and place the product in the target register. The immediate is sign extended to the machine width. Values are treated as signed integers.

Instruction Format: RI

31 30	29 27	26	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{9,0}	Ra ₅	Rt ₅	6 ₇				

Clock Cycles: 1

Execution Units: All ALU's

Operation:

$$Rt = Ra * \text{immediate}$$

Exceptions:

Notes:

MULSU – Multiply Signed Unsigned

Description:

Multiply two registers and place the product in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers. The first operand is signed, the second unsigned.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	S ₄	Rb ₅	Ra ₅	Rt ₅	22 ₇

Operation: R2

$$Rt = Ra * Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MULSUH – Multiply Signed Unsigned High

Description:

Multiply two registers and place the high order product bits in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers. The first operand is signed, the second unsigned.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	13 ₄	Rb ₅	Ra ₅	Rt ₅	22 ₇

Operation: R2

$$Rt = Ra * Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MULU – Unsigned Multiply Register-Register

Description:

Multiply two registers and place the product in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers. Values are treated as unsigned integers.

Instruction Format: R2

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	3 ₄	Rb ₅	Ra ₅	Rt ₅	22 ₇					

Operation: R2

$$Rt = Ra * Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MULUH – Unsigned Multiply High

Description:

Multiply two registers and place the high order product bits in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers. Values are treated as unsigned integers.

Instruction Format: R2

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	11 ₄	Rb ₅	Ra ₅	Rt ₅	22 ₇					

Operation: R2

$$Rt = Ra * Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

MULUI - Multiply Unsigned Immediate

Description:

Multiply a register and immediate value and place the product in the target register. The immediate is sign extended to the machine width. Values are treated as unsigned integers.

Instruction Format: RI

31 30	29 27	26	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{9,0}	Ra ₅	Rt ₅	14 ₇				

Clock Cycles: 1

Execution Units: All ALU's

Operation:

$$Rt = Ra + \text{immediate}$$

Exceptions:

Notes:

MUX – Multiplex

Description:

If a bit in Ra is set then the bit of the target register is set to the corresponding bit in Rb, otherwise the bit in the target register is set to the corresponding bit in Rc.

Instruction Format: BITFLD

MUX Rt, Ra, Rb, Rc

47 45	44 42	41 39	38	37	3635	34 29	28	24	2322	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	O ₃	0	0	Ot ₂	~ ₆	Rc ₅	~ ₂	Rb ₅	Ra ₅	Rt ₅	100 ₇					

Clock Cycles: 1

Execution Units: ALU #0 only

Operation:

For n = 0 to 63

 If Ra_[n] is set then

 Rt_[n] = Rb_[n]

 else

 Rt_[n] = Rc_[n]

Exceptions: none

NAND – Bitwise Nand

Description:

Bitwise nand two registers and place the result in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	0 ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇					

Operation: R2

$$Rt = \sim(Ra \& Rb)$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

NOR – Bitwise Or

Description:

Bitwise nor two registers and place the result in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	9 ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇					

Operation: R2

$$Rt = \sim(Ra \mid Rb)$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

OR – Bitwise Or

Description:

Bitwise or two registers and place the result in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	I ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇					

Operation: R2

$$Rt = Ra \mid Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

ORI - Or Immediate

Description:

Or a register and immediate value and place the sum in the target register. The immediate is sign extended to the machine width.

Instruction Format: RI

31 30	29 27	26	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	Immediate _{9,0}	Ra ₅	Rt ₅	9 ₇				

Clock Cycles: 1

Execution Units: All ALU's

Operation:

$$Rt = Ra + \text{immediate}$$

Exceptions:

Notes:

PFX – Constant Postfix

Description:

The PFX instruction postfix is used to provide large constants for use in the preceding instruction as the immediate constant for the instruction. The constant postfix may override the second source operand of most instructions. There are eight postfix instructions which provide constants of different lengths.

Postfixes are normally caught at the decode stage and do not progress further in the pipeline. They are treated as a NOP instruction.

Instruction Format: PFX0

This format provides an eight-bit constant, and sign extends the value to the width of the constant prefix buffer.

15	8	7	6	0
Immediate ₈	0	1	2	4 ₇

Instruction Format: LPFX0

This format provides a twenty-four-bit constant, and sign extends the value to the width of the constant prefix buffer.

31	8	7	6	0
Immediate ₂₄	1	2	3	4 ₇

Instruction Format: PFX1

This format provides a forty-bit constant, and sign extends the value to the width of the constant prefix buffer.

47	8	7	6	0
Immediate ₄₀	0	1	2	3 ₇

Instruction Format: LPFX1

This format provides a fifty-six-bit constant, and sign extends the value to the width of the constant prefix buffer.

63	8	7	6	0
Immediate ₅₆	1	2	3	4 ₇

Instruction Format: PFX2

This format provides a seventy-two-bit constant, and sign extends the value to the width of the constant prefix buffer.

**Instruction Format: LPFX2**

This format provides an eighty-eight-bit constant, and sign extends the value to the width of the constant prefix buffer.

**Instruction Format: PFX3**

This format provides a 104-bit constant, and sign extends the value to the width of the constant prefix buffer.

**Instruction Format: LPFX3**

This format provides a 128-bit constant, and sign extends the value to the width of the constant prefix buffer.

PTRDIF – Difference Between Pointers

Description:

Subtract two values then shift the result right. Both operands must be in a register. The right shift is provided to accommodate common object sizes. It may still be necessary to perform a divide operation after the PTRDIF to obtain an index into odd sized or large objects. Sc may vary from zero to fifteen.

Instruction Format: BITFLD

PTRDIF Rt, Ra, Rb, Rc

47 45	44 42	41 39	38	37	3635	3431	30	24	2322	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	l ₃	Ci	0	O ₂	~ ₄	Rc ₇	~ ₂	Rb ₅	Ra ₅	Rt ₅	100 ₇					

Operation:

$$Rt = \text{Abs}(Ra - Rb) \gg Rc_{[3:0]}$$

Clock Cycles: 1

Execution Units: Integer

Exceptions:

None

REVBIT – Reverse Bit Order

Description:

This instruction reverses the order of bits in Ra and stores the result in Rt.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	S ₅	Ra ₅	Rt ₅	lh ₇

Operation:

Execution Units: I

Clock Cycles: 1

Exceptions: none

Notes:

SEQ – Set if Equal

Description:

Compare two source operands for equality and place the result in the target register. The result is a Boolean true or false.

Operation:

$Rt = Ra == Rb$ or $Rt = Ra == Imm$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: R2

SEQ Rt, Ra, Rb

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	0 ₄	Rb ₅	Ra ₅	Rt ₅	20 ₇

Fmt ₃	Pr ₃	0 ₄	0 ₅	Ra ₅	Rt ₅	20 ₇
Immediate ₂₄					252 ₈	

SLE – Set if Less Than or Equal

Description:

Compare two source operands for signed less than or equal and place the result in the target register. The result is a Boolean true or false.

Operation:

$Rt = Ra \leq Rb$ or $Rt = Ra \leq Imm$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: R2

SLE Rt, Ra, Rb

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	3 ₄	Rb ₅	Ra ₅	Rt ₅	20 ₇	

SLEU – Set if Unsigned Less Than or Equal

Description:

Compare two source operands for unsigned less than or equal and place the result in the target register. The result is a Boolean true or false.

Operation:

$Rt = Ra \leq Rb$ or $Rt = Ra \leq Imm$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: R2

SLEU Rt, Ra, Rb

Fmt ₃	Pr ₃	S ₄	Rb ₅	Ra ₅	Rt ₅	20 ₇	

SLT – Set if Less Than

Description:

Compare two source operands for signed less than and place the result in the target register. The result is a Boolean true or false.

Operation:

$R_t = R_a < R_b$ or $R_t = R_a < \text{Imm}$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: R2

SLT R_t , R_a , R_b

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	2 ₄	Rb ₅	Ra ₅	Rt ₅	20 ₇					

SLTU – Set if Unsigned Less Than

Description:

Compare two source operands for unsigned less than and place the result in the target register.
The result is a Boolean true or false.

Operation:

$R_t = R_a < R_b$ or $R_t = R_a < Imm$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: R2

SLTU R_t , R_a , R_b

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	4 ₄	Rb ₅	Ra ₅	Rt ₅	20 ₇

SNE – Set if Not Equal

Description:

Compare two source operands for inequality and place the result in the target register. The result is a Boolean true or false.

Supported Operand Sizes: .b, .w, .t, .o, .h, .d

Operation:

$Rt = Ra \neq Rb$ or $Rt = Ra \neq Imm$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: R2

SNE Rt, Ra, Rb

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	1 ₄	Rb ₅	Ra ₅	Rt ₅	20 ₇

SQRT – Square Root

Description:

This instruction computes the integer square root of the contents of the source operand and places the result in Rt.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	4 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

$Rt = \text{SQRT}(Ra)$

Execution Units: Integer ALU #0

Clock Cycles: 1

Exceptions: none

Notes:

SUB – Subtract Register-Register

Description:

Subtract two registers and place the difference in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. All registers are integer registers.

Instruction Format: R2

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	5 ₄	Rb ₅	Ra ₅	Rt ₅	2h ₇					

Operation: R2

$$Rt = Ra - Rb$$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

WYDENDX – Wyde Index

Description:

This instruction searches Ra, which is treated as an array of wydes, for a wyde value specified by Rb and places the index of the wyde into the target register Rt. If the wyde is not found -1 is placed in the target register. A common use would be to search for a null. The index result may vary from -1 to +7. The index of the first found wyde is returned (closest to zero).

Supported Operand Sizes: .b, .t

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	6 ₄	Rb ₅	Ra ₅	Rt ₅	3 ₇

Operation:

Rt = Index of (Rb in Ra)

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Shift and Rotate Operations

Shift instructions can take the place of some multiplication and division instructions. Some architectures provide shifts that shift only by a single bit. Others use counted shifts, the original 80x88 used multiple clock cycles to shift by an amount stored in the CX register. Table 888 and Thor use a barrel shifter to allow shifting by an arbitrary amount in a single clock cycle. Shifts are infrequently used, and a barrel (or funnel) shifter is relatively expensive in terms of hardware resources.

Thor2024 has a full complement of shift instructions including rotates.

ASL –Arithmetic Shift Left

Description:

Left shift an operand value by an operand value and place the result in the target register. The ‘B’ field of the instruction is shifted into the least significant bits. The first operand must be in a register specified by the Ra. The second operand may be either a register specified by the Rb field of the instruction, or an immediate value.

Instruction Format: R2

31 29	28 26	25	24	23 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	B	0	~2	Rb ₅	Ra ₅	Rt ₅	88 ₇				

Operation:

$$Rt = Ra \ll Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

ASLI –Arithmetic Shift Left

Description:

Left shift an operand value by an operand value and place the result in the target register. The ‘B’ field of the instruction is shifted into the least significant bits. The first operand must be in a register specified by the Ra. The second operand is an immediate value.

Instruction Format: RIS

The RIS format shifts a target register by a small immediate constant.

15	12	11	7	6	0
Imm _{3..0}	Rt ₅	17 ₇			

Instruction Format: RI7

31	30	29	27	26	25	24	23	17	16	12	11	7	6	0

Operation:

$$Rt = Ra \ll Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

ASR –Arithmetic Shift Right

Description:

Right shift an operand value by an operand value and place the result in the target register. The sign bit is shifted into the most significant bits. The first operand must be in a register specified by the Ra. The second operand may be either a register specified by the Rb field of the instruction, or an immediate value.

Instruction Format: R2

31 29	28 26	25	24	23 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	0	0	~ ₂	Rb ₅		Ra ₅		Rt ₅			90 ₇

Operation:

$$Rt = Ra \ll Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

ASRI –Arithmetic Shift Right

Description:

Right shift an operand value by an operand value and place the result in the target register. The sign bit is shifted into the most significant bits. The first operand must be in a register specified by the Ra. The second operand is an immediate value.

Instruction Format: RI7

31 30	29 27	26	25	24	23	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	0	B	1	Immediate _{6..0}		Ra ₅		Rt ₅		90 ₇	

Operation:

$$Rt = Ra \gg Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

LSR –Logic Shift Right

Description:

Right shift an operand value by an operand value and place the result in the target register. The ‘B’ field of the instruction is shifted into the most significant bits. The first operand must be in a register specified by the Ra. The second operand may be either a register specified by the Rb field of the instruction, or an immediate value.

Instruction Format: R2

31 29	28 26	25	24	23 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	B	0	~2	Rb ₅	Ra ₅	Rt ₅	89 ₇				

Operation:

$$Rt = Ra \gg Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

LSRI –Logical Shift Right

Description:

Right shift an operand value by an operand value and place the result in the target register. The ‘B’ field of the instruction is shifted into the most significant bits. The first operand must be in a register specified by the Ra. The second operand is an immediate value.

Instruction Format: RI7

31 30	29 27	26	25	24	23	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	0	B	1	Immediate _{6..0}		Ra ₅		Rt ₅		89 ₇	

Operation:

$$Rt = Ra \gg Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

ROL –Rotate Left

Description:

Rotate left an operand value by an operand value and place the result in the target register. The most significant bits are shifted into the least significant bits. The first operand must be in a register specified by the Ra. The second operand may be either a register specified by the Rb field of the instruction, or an immediate value.

Instruction Format: R2

31 29	28 26	25	24	23 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	B	0	~ ₂	Rb ₅	Ra ₅	Rt ₅	91 ₇				

Operation:

$$Rt = Ra \ll Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

ROLI –Rotate Left by Immediate

Description:

Rotate left shift an operand value by an operand value and place the result in the target register. The most significant bits are shifted into the least significant bits. The first operand must be in a register specified by the Ra. The second operand is an immediate value.

Instruction Format: RI7

31 30	29 27	26	25	24	23	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	0	B	1	Immediate _{6..0}		Ra ₅		Rt ₅		91 ₇	

Operation:

$$Rt = Ra \ll Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

ROR –Rotate Right

Description:

Rotate right an operand value by an operand value and place the result in the target register. The least significant bits are shifted into the most significant bits. The first operand must be in a register specified by the Ra. The second operand may be either a register specified by the Rb field of the instruction, or an immediate value.

Instruction Format: R2

31 29	28 26	25	24	23 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	B	0	~ ₂	Rb ₅		Ra ₅		Rt ₅			92 ₇

Operation:

$$Rt = Ra \gg Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

RORI –Rotate Right by Immediate

Description:

Rotate right an operand value by an operand value and place the result in the target register. The least significant bits are shifted into the most significant bits. The first operand must be in a register specified by the Ra. The second operand is an immediate value.

Instruction Format: RI7

31	30	29	27	26	25	24	23	17	16	12	11	7	6	0
Fmt ₂	Pr ₃	0	B	1	Immediate _{6..0}				Ra ₅	Rt ₅		92 ₇		

Operation:

$$Rt = Ra \gg Rb$$

Operation Size: .o

Execution Units: integer ALU

Exceptions: none

Example:

Bit-field Manipulation Operations

Many CPUs do not have direct support for bit-field manipulation. Instead, they rely on ordinary logical and shift operations. The benefit of having bit-field operations is that they are more code dense than performing the operations using other ALU ops.

The beginning and end of a bitfield may be specified as either a pair of immediate constants or in a pair of registers.

General Format of Bitfield Instructions

Bitfield instructions are 48-bits in length to accommodate register and immediate constants.

CLR Rt, Ra, Rb, Rc

47 45	44 41	40 38	37	36	35 34	33 32	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₄	Fn ₃	Ci	Bi	Ot ₂	~ ₂	Me ₇		Mb ₇		Ra ₅		Rt ₅			93 ₇

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

The Ot₂ field determines the operand type for operands Ra and Rt.

Ot ₂	Ra, Rt
0	Integer
1	Float
2	predicate
3	reserved

CLR – Clear Bit Field

Description:

A bit field in the source operand is cleared and the result placed in the target register.

Operation:

Instruction Format: BITFLD

CLR Rt, Ra, Rb, Rc

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	0 ₃	Ci	Bi	Ot ₂	~ ₄	Me ₇		Mb ₇		Ra ₅		Rt ₅			104 ₇

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

COM – Complement Bit Field

Description:

A bit field in the source operand is one's complemented and the result placed in the target register.

Operation:

Instruction Format: BITFLD

COM Rt, Ra, Rb, Rc

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	2 ₃	Ci	Bi	Ot ₂	~ ₄	Me ₇		Mb ₇		Ra ₅		Rt ₅			104 ₇

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

EXT – Extract Bit Field

Description:

A bit field is extracted from the source operand, sign extended, and the result placed in the target register.

Operation:

Instruction Format: BITFLD

COM Rt, Ra, Rb, Rc

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	5 ₃	Ci	Bi	Ot ₂	~ ₄	Me ₇		Mb ₇		Ra ₅		Rt ₅			104 ₇

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

EXTU – Extract Unsigned Bit Field

Description:

A bit field is extracted from the source operand, zero extended, and the result placed in the target register.

Operation:

Instruction Format: BITFLD

EXTU Rt, Ra, Rb, Rc

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	4 ₃	Ci	Bi	Ot ₂	~ ₄	Me ₇		Mb ₇		Ra ₅		Rt ₅			104 ₇

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

SET – Set Bit Field

Description:

A bit field in the source operand is set to all ones and the result placed in the target register.

Operation:

Instruction Format: BITFLD

CLR Rt, Ra, Rb, Rc

47 45	44 42	41 39	38	37	36 35	34 31	30	24	23	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	I ₃	Ci	Bi	Ot ₂	~ ₄	Me ₇		Mb ₇		Ra ₅		Rt ₅			104 ₇

Mb₇ may be either a register spec or a seven-bit immediate constant specifying the start position of the bitfield.

Me₇ may be either a register spec or a seven-bit immediate constant specifying the end position of the bitfield.

The Ci field indicates (1) to use either an immediate constant, or (0) to use a register for the third source operand.

The Bi field indicates (1) to use either an immediate constant, or (0) to use a register for the second source operand.

Ot₂ indicates to use predicate registers for the Ra and Rt operands.

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Cryptographic Accelerator Instructions

AES64DS – Final Round Decryption

Description:

Perform the final round of decryption for the AES standard. Register Ra represents the entire AES state.

Instruction Format: R1

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	~ ₄	18 ₅	Ra ₅	Rt ₅	lh ₇					

Operation:

Exceptions: none

AES64DSM – Middle Round Decryption

Description:

Perform a middle round of decryption for the AES standard. Register Ra represents the entire AES state.

Instruction Format: R1

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	~ ₄	19 ₅	Ra ₅	Rt ₅	lh ₇					

Operation:

Exceptions: none

AES64ES – Final Round Encryption

Description:

Perform the final round of encryption for the AES standard. Register Ra represents the entire AES state.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	20 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

Exceptions: none

AES64ESM – Middle Round Encryption

Description:

Perform a middle round of encryption for the AES standard. Register Ra represents the entire AES state.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	21 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

Exceptions: none

SHA256SIG0

Description:

Implements the Sigma0 transformation function used in the SHA2-256 and SHA2-224 hash function. Only the low order 32 bits of Ra are operated on. The 32-bit result is sign extended to the machine width.

Instruction Format: R1

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	~ ₄	24 ₅	Ra ₅	Rt ₅	1h ₇					

Operation:

$$Rt = \text{sign_extend}(\text{ror32}(Ra, 7) \wedge \text{ror32}(Ra, 18) \wedge (Ra_{32} \gg 3))$$

Execution Units: ALU #0

Exceptions: none

SHA256SIG1

Description:

Implements the Sigma1 transformation function used in the SHA2-256 and SHA2-224 hash function. Only the low order 32 bits of Ra are operated on. The 32-bit result is sign extended to the machine width.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	25 ₅	Ra ₅	Rt ₅	lh ₇

Clock Cycles: 1

Operation:

$$Rt = \text{sign_extend}(\text{ror32}(Ra, 17) \wedge \text{ror32}(Ra, 19) \wedge (Ra_{32} \gg 10))$$

Execution Units: ALU #0

Exceptions: none

SHA256SUM0

Description:

Implements the Sum0 transformation function used in the SHA2-256 and SHA2-224 hash function. Only the low order 32 bits of Ra are operated on. The 32-bit result is sign extended to the machine width.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~4	26 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

$$Rt = \text{sign_extend}(\text{ror32}(Ra, 2) \wedge \text{ror32}(Ra, 13) \wedge \text{ror32}(Ra, 22))$$

Execution Units: ALU #0

Exceptions: none

SHA256SUM1

Description:

Implements the Sum1 transformation function used in the SHA2-256 and SHA2-224 hash function. Only the low order 32 bits of Ra are operated on. The 32-bit result is sign extended to the machine width.

Instruction Format: R1

31 29	28	26	25 22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	~4	27 ₅	Ra ₅	Rt ₅	1h ₇					

Operation:

$$Rt = \text{sign_extend}(\text{ror32}(Ra, 6) \wedge \text{ror32}(Ra, 11) \wedge \text{ror32}(Ra, 25))$$

Execution Units: ALU #0

Exceptions: none

SHA512SIG0

Description:

Implements the Sigma0 transformation function used in the SHA2-512 hash function.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	28 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

$$Rt = \text{ror64}(Ra, 1) \wedge \text{ror64}(Ra, 8) \wedge (Ra \gg 7)$$

Execution Units: ALU #0

Exceptions: none

SHA512SIG1

Description:

Implements the Sigma1 transformation function used in the SHA2-512 hash function.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	29 ₅	Ra ₅	Rt ₅	lh ₇

Operation:

$$Rt = \text{ror64}(Ra, 19) \wedge \text{ror64}(Ra, 61) \wedge (Ra \gg 6)$$

Execution Units: ALU #0

Exceptions: none

SHA512SUM0

Description:

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	30 ₅	Ra ₅	Rt ₅	lh ₇

SHA512SUM1

Description:

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	31 ₅	Ra ₅	Rt ₅	lh ₇

SM3P0

Description:

P0 transform of SM3 hash function.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	~ ₄	14 ₅	Ra ₅	Rt ₅	1h ₇	

Operation

$$Rt = Ra \wedge \text{rol}(Ra, 9) \wedge \text{rol}(Ra, 17)$$

SM3P1

Description:

P1 transform of SM3 hash function.

Instruction Format: R1

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	~ ₄	15 ₅	Ra ₅	Rt ₅	1h ₇	

Operation

$$R_t = R_a \wedge \text{rol}(R_a, 15) \wedge \text{rol}(R_a, 23)$$

Floating-Point Operations

Precision

Floating point operations are always performed at the greatest precision available. Lower precision formats are available for storage.

For decimal floating-point three storage formats are supported. 96-bit triple precision, 64-bit double precision, and 32-bit single precision values.

Representations

Binary Floats

Triple Precision, Float:128

The core uses a 128-bit quad precision binary floating-point representation.

Quad Precision, long double

Double Precision, double

Single Precision, float

Half Precision, short float

Decimal Floats

The core uses a 128-bit densely packed decimal triple precision floating-point representation.

The significand stores 34 densely packed decimal digits. One whole digit before the decimal point.

The exponent is a power of ten as a binary number with an offset of 1535. Range is 10^{-1535} to 10^{1536}

64-bit double precision decimal floating point:

The significand stores 16 DPD digits. One whole digit before the decimal point.

32-bit single precision decimal floating point:

The significand store 7 DPD digits. One whole digit before the decimal point.

Rounding Modes

Binary Float Rounding Modes

Rm3	Rounding Mode
000	Round to nearest ties to even
001	Round to zero (truncate)
010	Round towards plus infinity
011	Round towards minus infinity
100	Round to nearest ties away from zero
101	Reserved
110	Reserved
111	Use rounding mode in float control register

Decimal Float Rounding Modes

Rm3	Rounding Mode
000	Round ceiling
001	Round floor
010	Round half up
011	Round half even
100	Round down
101	Reserved
110	Reserved
111	Use rounding mode in float control register

FABS – Absolute Value

Description:

This instruction computes the absolute value of the contents of the source operand and places the result in Rt. The sign bit of the value is cleared. No rounding occurs.

Integer Instruction Format: R1

FABS Ft, Fa

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	~ ₄	0 ₅	Fa ₅	Ft ₅	97 ₇

Clock Cycles: 1

Operation:

$$Ft = \text{Abs}(Fa)$$

Execution Units: FPU #0

Clock Cycles: 1

Exceptions: none

Notes:

FADD –Float Addition

Description:

Add two source operands and place the sum in the target register. All registers values are treated as quad precision floating-point values. An immediate value is converted to quad precision value from half, single, or double precision.

Supported Operand Sizes:

Operation:

$$Ft = Fa + Fb \text{ or } Ft = Fa + \text{Imm}$$

Clock Cycles: 8

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FLT2

FADD Ft, Fa, Fb

31 29	28 26	25 22	21 17	16 12	11 7	6 0
Fmt ₃	Pr ₃	4 ₄	Fb ₅	Fa ₅	Ft ₅	98 ₇

FADDI –Float Add Immediate

Description:

Add two source operands and place the sum in the target register. All registers values are treated as quad precision floating-point values. An immediate value is converted to quad precision value from half, single, or double precision.

Supported Operand Sizes:

Operation:

$$Ft = Fa + Fb \text{ or } Ft = Fa + Imm$$

Clock Cycles: 8

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FRI

FADDI Ft, Fa, Imm

4746	4543	4240	3936	3533	32	17	1612	117	6	0
Fmt ₂	Pr ₃	Rm ₃	4 ₄	~ ₃	Imm ₁₆	Fa ₅	Ft ₅	97 ₇		

FCMP - Comparison

Description:

Compare two source operands and place the result in the target register. The result is a vector identifying the relationship between the two source operands as floating-point values. This instruction may compare against lower precision immediate values to conserve code space. The source operands are quad precision floating-point values, the target operand is an integer register. No rounding occurs.

Supported Operand Sizes:

Operation:

$R_t = F_a ? F_b$ or $R_t = F_a ? \text{Imm}$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FLT2

FCMP R_t , R_a , R_b

31 29	28 26	25 22	21 17	16 12	11 7	6	0

FCMPI – Float Compare Immediate

Description:

Compare two source operands and place the result in the target register. The result is a vector identifying the relationship between the two source operands as floating-point values. This instruction may compare against lower precision immediate values to conserve code space. The source operands are quad precision floating-point values, the target operand is an integer register. No rounding occurs.

Supported Operand Sizes:

Operation:

$Rt = Fa \text{ ? Imm}$

Clock Cycles: 1

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FLT2

FCMPI Rt, Fa, Imm

FMUL –Float Multiplication

Description:

Multiply two source operands and place the product in the target register. All registers values are treated as quad precision floating-point values. An immediate value is converted to quad precision value from half, single, or double precision.

Operation:

$Rt = Ra * Rb$ or $Rt = Ra * Imm$

Clock Cycles: 8

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FLT2

FMUL Rt, Ra, Rb

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	6 ₄	Rb ₅	Ra ₅	Rt ₅	98 ₇	

FMULI –Float Multiply Immediate

Description:

Multiply two source operands and place the product in the target register. All registers values are treated as quad precision floating-point values. An immediate value is converted to quad precision value from half, single, or double precision.

Operation:

$$Rt = Ra * Imm$$

Clock Cycles: 8

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FRI

FMULI Rt, Ra, Imm

4746	4543	4240	3936	3533	32	17	1612	117	6	0
Fmt ₂	Pr ₃	Rm ₃	6 ₄	~ ₃	Imm ₁₆		Ra ₅	Rt ₅		97 ₇

FSCALEB –Scale Exponent

Description:

Add the source operand to the exponent. The second source operand is an integer value. No rounding occurs.

Instruction Formats:

FSCALEB Ft, Fa, Rb

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	0 ₄	Rb ₅	Fa ₅	Ft ₅	98 ₇	

Operation:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

FSCALEBI –Scale Exponent Immediate

Description:

Add the source operand to the exponent. The second source operand is an integer value. No rounding occurs.

Instruction Formats:

FSCALEB Ft, Fa, Imm

4746	4543	4240	3936	3533	32	17	1612	117	6	0
Fmt ₂	Pr ₃	~ ₃	0 ₄	~ ₃	Imm ₁₆	Fa ₅	Ft ₅	97 ₇		

Operation:

Clock Cycles:

Execution Units: All Integer ALU's

Exceptions: none

Notes:

FSEQ – Float Set if Equal

Description:

Compares two source operands for equality and places the result in the target register. The target register is a predicate register. The result is a Boolean true or false. Positive and negative zero are considered equal. 16, 32, 64, and 128-bit immediates are supported. For FSEQ if either operand is a NaN zero the result is false. No rounding occurs.

Operation:

$\text{Prt} = \text{Fa} == \text{Fb}$ or $\text{Prt} = \text{Fa} == \text{Imm}$

Clock Cycles: 1

Execution Units: All FPU's

Exceptions: none

Notes:

Instruction Formats:

FSEQ Prt, Ra, Rb

31 29	28 26	25 22	21 17	16 12	11	10 7	6	0
Fmt ₃	Pr ₃	8 ₄	Fb ₅	Fa ₅	~	Pt ₄	98 ₇	

FSNE – Float Set if Not Equal

Description:

Compares two source operands for equality and places the result in the target predicate register. The result is a Boolean true or false. Positive and negative zero are considered equal. 16, 32, 64, and 128-bit immediates are supported. No rounding occurs.

Operation:

$\text{Prt} = \text{Fa} \neq \text{Fb}$ or $\text{Prt} = \text{Fa} \neq \text{Imm}$

Clock Cycles: 1

Execution Units: All FPU's

Exceptions: none

Notes:

Instruction Formats:

FSNE Ft, Fa, Fb

31 29	28 26	25 22	21 17	16 12	11	10 7	6	0
Fmt ₃	Pr ₃	9 ₄	Fb ₅	Fa ₅	~	Pt ₄	98 ₇	

FSUB –Float Subtraction

Description:

Subtract two source operands and place the difference in the target register. All registers values are treated as quad precision floating-point values. An immediate value is converted to quad precision value from half, single, or double precision.

Supported Operand Sizes:

Operation:

$$Ft = Fa - Fb \text{ or } Ft = Fa - \text{Imm}$$

Clock Cycles: 8

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FLT2

FSUB Ft, Fa, Fb

Fmt ₃	Pr ₃	5 ₄	Fb ₅	Fa ₅	Ft ₅	98 ₇

FSUBI –Float Subtract Immediate

Description:

Subtract two source operands and place the difference in the target register. All registers values are treated as quad precision floating-point values. An immediate value is converted to quad precision value from half, single, or double precision.

Supported Operand Sizes:

Operation:

$$Ft = Fa - Fb \text{ or } Ft = Fa - Imm$$

Clock Cycles: 8

Execution Units: All Integer ALU's

Exceptions: none

Notes:

Instruction Format: FRI

FSUBI Ft, Fa, Imm

4746	4543	4240	3936	3533	32	17	1612	117	6	0
Fmt ₂	Pr ₃	Rm ₃	5 ₄	~ ₃	Imm ₁₆	Fa ₅	Ft ₅	97 ₇		

Decimal Floating-Point Instructions

DFADD – Add Register-Register

Description:

Add two registers and place the sum in the target register. If the instruction is a vector addition then Ra and Rt are vector registers. Rb may be either a vector or a scalar register. The values are treated as quad precision decimal floating-point values.

Instruction Format: R2

31 29	28 26	25 22	21 17	16 12	11 7	6	0
Fmt ₃	Pr ₃	4 ₄	Fb ₅	Fa ₅	Ft ₅	102 ₇	

Execution Units: All ALU's

Operation:

$$Rt = Ra + Rb$$

Exceptions:

Notes:

Load / Store Instructions

Overview

Addressing Modes

Load and store instructions have two addressing modes, register indirect with displacement and indexed addressing.

For vector indexed addressing Ra acts as a base address register. If Rb is a scalar value then it is used to increment the load / store address according to the vector element. Otherwise, if Rb is a vector value it is used directly as an index.

The 'C' bit of the instruction indicates the vector is compressed in memory. When compressed, for stores if a mask bit is clear then no value is stored to memory and the memory address does not increment. Loads are similar.

Load Formats

Register Indirect with Displacement Format

For register indirect with displacement addressing the load or store address is the sum of a register Ra and a displacement constant found in the instruction.

Instruction Format: d[Rn]

31	30	29	26	25	19	18	17	16	12	11	7	6	0
Fmt ₂	Pr ₄	Disp _{6..0}	Ot ₂	Ra ₅	Rt ₅	64 ₇							

Instruction Format: d[Ra+Rb*Sc]

47	45	44	41	40	36	35	34	33	32	31	25	24	22	22	17	16	12	11	7	6	0
Fmt ₂	Pr ₄	Fn ₅	Ot ₂	Ca ₂	Disp _{6..0}	Sc ₃	Rb ₅	Ra ₅	Rt ₅	79 ₇											

Store Formats

Register Indirect with Displacement Format

For register indirect with displacement addressing the load or store address is the sum of a register Ra and a displacement constant found in the instruction.

47	19	18	14	13	9	8	7	0
Displacement _{28..0}	Ra ₅	Rs ₅	0	Opcode ₈				

Indexed Format

31	29	28	27	26	25	24	23	19	18	14	13	9	8	7	0
m ₃	z	C	~2	Tb	Rb ₅	Ra ₅	Rs ₅	v	Opcode ₈						

CACHE <cmd>,<ea>

Description:

Issue command to cache controller.

Instruction Format: d[Rn]

31 30	29 26	25	17	16	12	11	7	6	0
Fmt ₂	Pr ₄	Immediate _{8,0}	Ra ₅	Cmd ₅	75 ₇				

Instruction Format: d[Ra+Rb*]

31 30	29 26	25 24	22	22	17	16	12	11	7	6	0
Fmt ₂	Pr ₄	3 ₂	Sc	Rb ₅	Ra ₅	Cmd ₅	78 ₇				

Notes:

Cmd ₅	Cache	
???00	Ins.	Invalidate cache
???01	Ins.	Invalidate line
???10	TLB	Invalidate TLB
???11	TLB	Invalidate TLB entry
000??	Data	Invalidate cache
001??	Data	Invalidate line
010??	Data	Turn cache off
011??	Data	Turn cache on

Block Instructions

BFND – Block Find

Description:

This instruction compares data from the memory location to the data in register Rs. A target predicate register is set if the data is found.

Instruction Format: d[Ra+Rb*Sc]

47 45	44 41	40 36	35 34	33 30	29 28	27 25	24 22	22 17	16 12	11 7	6 0
Fmt ₂	Pr ₄	28 ₅	Ot ₂	Pt ₄	Bi ₂	Sz ₃	Sc ₃	Rb ₅	Ra ₅	Rs ₅	79 ₇

Bi ₂	Rb
0	No Change
1	Increment by 64
2	Decrement by 64
3	reserved

Execution Units: Memory

Operation:

Vector Specific Instructions

MFVL – Move from Vector Length

Description:

This instruction moves the vector length register to a general-purpose register.

Instruction Format: MFVL

15	12	11	7	6	0
15 ₄	Rt ₅	119 ₇			

Operation:

$Rt = VL$

MTVL – Move to Vector Length

Description:

This instruction moves a general-purpose register to the vector length register. Moving a value larger than the maximum vector length of the machine will result in setting the vector length to the maximum vector length.

Instruction Format: MFLK

15	12	11	7	6	0
7 ₄	Rs ₅	119 ₇			

Operation:

$VL = \min(Rs, \text{maximum vector length})$

V2BITS

Description

Convert Boolean vector to bits. A bit specified by Rb or an immediate of each vector element is copied to the bit corresponding to the vector element in the target register. The target register is a scalar register or a predicate register. Usually, Rb would be zero so that the least significant bit of the vector is copied.

A typical use is in moving the result of a vector set operation into a predicate register.

Instruction Format: R2

V2BITS Rt, Ra, Rb

31	29	28	26	25	22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	0 ₄	Rb ₅	Ra ₅	Rt ₅	18 ₇							

V2BITS Prt, Ra, Rb

31	29	28	26	25	22	21	17	16	12	11	10	7	6	0
Fmt ₃		Pr ₃		6 ₄		Rb ₅		Ra ₅		~	Prt ₄		18 ₇	

Operation

For x = 0 to VL-1

$$Rt.bit[x] = Ra[x].bit[Rb]$$

Exceptions: none

Example:

```

cmp v1,v2,v3      ; compare vectors v2 and v3
v2bits pr1,v1,#8  ; move NE status to bits in m1
vadd v4,v5,v6,pr1  ; perform some masked vector operations
vmuls v7,v8,v9,pr1
vadd v7,v7,v4,pr1
  
```

VEINS / VMOVSV – Vector Element Insert

Synopsis

Vector element insert.

Description

A general-purpose register Ra is transferred into one element of a vector register Vt. The element to insert is identified by Rb.

Instruction Format: R2

31	29	28	26	25	22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	3 ₄	Rb ₅	Ra ₅	Vt ₅	18 ₇							

Operation

$Vt[Rb] = Ra$

Exceptions: none

VEX / VMOVS – Vector Element Extract

Synopsis

Vector element extract.

Description

A vector register element from Va is transferred into a general-purpose register Rt. The element to extract is identified by Rb. Rb and Rt are scalar registers.

Instruction Format: R2

31	29	28	26	25	22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	2 ₄	Rb ₅	Va ₅	Rt ₅	18 ₇							

Operation

$Rt = Va[Rb]$

Exceptions: none

VGIDX – Generate Index

Description

A value in a register Ra is multiplied by the element number and added to a value in Rb and copied to elements of vector register Vt guided by a vector mask register. Ra is a scalar register. This operation may be used to compute memory addresses for a subsequent vector load or store operation. Only the low order 24-bits of Ra are involved in the multiply. The result of the multiply is a product less than 41 bits in size. The multiply is a fast 24x16 bit multiply.

Instruction Format: R2

31	29	28	26	25	22	21	17	16	12	11	7	6	0
Fmt ₃	Pr ₃	4 ₄	Rb ₅	Ra ₅	Vt ₅	18 ₇							

Operation

y = 0

for x = 0 to VL - 1

if (Pr[x])

Vt[y] = Ra * y + Rb

y = y + 1

Predicate Operations

MFPR – Move from Predicate

Description

Move a predicate register to a general-purpose register.

Instruction Format: PR2

31 29	28 25	24 21	20 19	18 15	14 12	11 7	6	0
\sim_3	Pr ₄	11 ₄	\sim_2	Prb ₄	\sim_3	Rt ₅	48h ₈	

Operation

Rt = Pr

Execution Units: ALUs

MTPR – Move to Predicate

Description

Move a general-purpose register to a predicate register.

Instruction Format: PR2

31 29	28 25	24 21	20 17	16 12	11	10 7	6	0
\sim_3	Pr ₄	12 ₄	\sim_4	Ra ₅	\sim	Prt ₄	48h ₈	

Operation

Prt = Ra

Execution Units: ALUs

PRADD – Predicate Add

Description:

Add the contents of two predicate registers and place the result in a predicate register.

Instruction Format: VMR2

31 29	28 25	24 21	20 19	18 15	14 11	10 7	6	0
\sim_3	Pr ₄	4 ₄	\sim_2	Prb ₄	Pra ₄	Prt ₄	48h ₈	

1 clock cycle

Exceptions: none

PRAND – Predicate And

Description:

Bitwise ‘and’ the contents of two predicate registers and place the result in a predicate register.

Instruction Format: VMR2

31 29	28 25	24 21	20 19	18 15	14 11	10 7	6	0
\sim_3	Pr ₄	8 ₄	\sim_2	Prb ₄	Pra ₄	Prt ₄	48h ₈	

Exceptions: none

PRASL – Predicate Arithmetic Shift Left

Description:

Shift a predicate register to the left up to 63 bits.

Instruction Format: VMR2

31 29	28 25	24 21	20 15	14 11	10 7	6	0
\sim_3	Pr ₄	0 ₄	Amt ₆	Pra ₄	Prt ₄	48h ₈	

1 clock cycle

Exceptions: none

PRCNTPOP – Predicate Population Count

Description

Count the set bits in a predicate register and store result in a general-purpose register.

Instruction Format: PR2

31 29	28 25	24 21	20 19	18 15	14 12	11 7	6	0
\sim_3	Pr ₄	13 ₄	\sim_2	Prb ₄	\sim_3	Rt ₅	48h ₈	

Operation

$Rt = Pr$

Execution Units: ALUs

PREOR – Predicate Exclusive Or

Description:

Bitwise exclusive ‘or’ the contents of two predicate registers and place the result in a predicate register.

Instruction Format: VMR2

31 29	28 25	24 21	20 19	18 15	14 11	10 7	6	0
~ ₃	Pr ₄	10 ₄	~ ₂	Prb ₄	Pra ₄	Prt ₄	48h ₈	

Exceptions: none

PRFILL – Predicate Fill Mask

Description:

Generate a mask between Mb, mask begin, and Me, Mask End and store in predicate register.

Instruction Format: VMR2

31	29	28	25	24	18	17	11	10	7	6	0
~ ₃	Pr ₄	Me ₇	Mb ₇	Prt ₄	49h ₇						

1 clock cycle

Exceptions: none

PRFIRST – Find First Set Bit

Description

The position of the first bit set in the mask register is copied to the target register. If no bits are set the value is -1. The search begins at the least significant bit and proceeds to the most significant bit.

Instruction Format:

31 29 28 25 24 21 2019 18 15 14 12 11 7 6 0
~3 Pr4 144 ~2 Prb4 ~3 Rt5 48h8

Operation

$R_t = \text{first set bit number of } (Pr_b)$

Exceptions: none

Execution Units: ALUs

PRLAST – Find Last Set Bit

Description

The position of the last bit set in the predicate register is copied to the target register. If no bits are set the value is -1. The search begins at the most significant bit of the mask register and proceeds to the least significant bit.

Instruction Format:

31 29 28 25 24 21 2019 18 15 14 12 11 7 6 0
~ ₃ Pr ₄ 15 ₄ ~ ₂ Prb ₄ ~ ₃ Rt ₅ 48h ₈

Operation

Rt = last set bit number of (Prb)

Exceptions: none

Execution Units: ALUs

PRLSR – Predicate Logical Shift Right

Description:

Shift a predicate register to the left up to 31 bits.

Instruction Format: VMR2

31	29	28	25	24	21	20	15	14	11	10	7	6	0
\sim_3	Pr_4	2_4	Amt_6	Pra_4	Prt_4	48h_8							

1 clock cycle

Exceptions: none

PROR – Predicate Or

Description:

Bitwise ‘or’ the contents of two predicate registers and place the result in a predicate register.

Instruction Format: PR2

31 29	28 25	24 21	20 19	18 15	14 11	10 7	6	0
\sim_3	Pr ₄	9 ₄	\sim_2	Prb ₄	Pra ₄	Prt ₄	48h ₈	

Exceptions: none

PRROL – Predicate Rotate Left

Description:

Rotate a predicate register to the left up to 63 bits.

Instruction Format: VMR2

31	29	28	25	24	21	20	15	14	11	10	7	6	0
~ ₃	Pr ₄	1 ₄	Amt ₆	Pra ₄	Prt ₄	48h ₈							

1 clock cycle

Exceptions: none

PRROR – Predicate Rotate Right

Description:

Rotate a predicate register to the Right up to 63 bits.

Instruction Format:

31	29	28	25	24	21	20	15	14	11	10	7	6	0
\sim_3	Pr ₄	3 ₄	Amt ₆	Pra ₄	Prt ₄	48h ₈							

1 clock cycle

Exceptions: none

PRSUB – Predicate Subtract

Description:

Add the contents of two predicate registers and place the result in a predicate register.

Instruction Format: PR2

31 29	28 25	24 21	20 19	18 15	14 11	10 7	6	0
\sim_3	Pr ₄	5 ₄	\sim_2	Prb ₄	Pra ₄	Prt ₄	48h ₈	

1 clock cycle

Exceptions: none

Branch / Flow Control Instructions

Overview

Mnemonics

There are mnemonics for specifying the comparison method. Floating-point comparisons prefix the branch mnemonic with 'F' as in FBEQ. Decimal-floating point comparisons prefix the branch mnemonic with 'DF' as in DFBEQ. And finally posit comparisons prefix the branch mnemonic with a 'P' as in 'PBEQ'. Long branches are prefixed with an 'L' as in LDFBEQ

Conditions

Conditional branches branch to the target address only if the condition is true. The condition is determined by the comparison of two general-purpose registers or by the comparison of a general purpose register and a postfixed immediate constant.

The original Thor machine used instruction predicates to implement conditional branching. Another instruction was required to set the predicate before branching. Combining compare and branch in a single instruction may reduce the dynamic instruction count. An issue with comparing and branching in a single instruction is that it may lead to a wider instruction format.

The comparison used is determined by a three-bit field in the instruction. There are five comparison types that may be performed as outlined in the table below.

Cm ₃	Comparison Type
0	signed integer comparisons
1	quad float comparison
2	quad decimal float comparison
3	posit comparison
4	unsigned integer comparisons
5 to 7	reserved

Conditional Branch Format

Branches use 32 or 48-bit opcodes.

A 32-bit opcode does not leave a large enough target field for all cases and would end up using two or more instructions to implement most branches. With the prospect of using two instructions to perform compare then branches as many architectures do, it is more space efficient to simply use a wider instruction format.

47	23	22	18	17	13	12	10	9	8	7	6	0
Target ₂₅					Rb ₅		Ra ₅		Cm ₃	Lk ₂	1	2xh ₈

31	23	22	18	17	13	12	10	9	8	7	6	0
Target ₉					Rb ₅		Ra ₅		Cm ₃	Lk ₂	0	2xh ₈

Branch Conditions

The branch opcode determines the condition under which the branch will execute.

2x	Integer Comparison Test	Float / Decimal Float	Posit
28h	signed less than	less than	less than
29h	signed greater or equal	greater than or equal	greater than or equal
2Ah	signed less than or equal	less than or equal	less than or equal
2Bh	signed greater than	greater than	greater than
2Ch		magnitude less than	
2Dh			
2Eh			
2Fh			
26h	equal	equal	equal
27h	not equal	not equal	not equal
24h		ordered	
25h	bit set or clear	unordered	
22h	bit set or clear immediate	bit set or clear immediate	bit set or clear immediate

Linkage

Branches may specify a linkage register which is updated with the address of the next instruction. This allows subroutines to be called. There are three link registers in the architecture.

Lk ₂	Meaning
0	do not store return address
1	use Lk1 / Ca1
2	use Lk2 / Ca2
3	Use Lk3 / Ca3

Branch Target

For conditional branches, the target address is formed as the sum of the instruction pointer and a constant specified in the instruction. Long branches are IP relative with a range of $\pm 32\text{MB}$. Short branches are IP relative with a range of $\pm 512\text{B}$. The displacement field is shifted left once before use.

The target displacement field is recommended to be at least 16-bits. It is possible to get by with a displacement as small as 12-bits before a significant percentage of branches must be implemented as two or more instructions.

Branch to Register

The branch to register instruction allows a conditional return from subroutine to be used or a branch to a value in a register. Branching to a value in a register allows all bits of the instruction pointer to be set. Since addresses are formed as the sum of a code address register and a constant in the instruction, branching to a register is inherent in the instruction. The target constant may be set to zero. Specifying $\text{Ca} = 0$ will use the value zero rather than the contents of Ca zero. This allows absolute address branches to be formed.

BBC – Branch if Bit Clear

Description:

This instruction branches to the target address if bit Rb of Ra is clear, otherwise program execution continues with the next instruction. For a further description see Branch Instructions.

Formats Supported: B

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}				Rb ₅		Ra ₅		0 ₃		Lk ₂	1	25h ₆

Operation:

Lk = next IP

If (Ra.bit[Rb] == 0)

IP = IP + Constant

Execution Units: Branch

Exceptions: none

Notes:

BBCI – Branch if Bit Clear Immediate

Description:

This instruction branches to the target address if a bit specified in an immediate field of the instruction of Ra is set, otherwise program execution continues with the next instruction. For a further description see Branch Instructions.

Formats Supported: B

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}				Imm ₅		Ra ₅		0 ₃		Lk ₂	1	22h ₇

Operation:

Lk = next IP

If (Ra.bit[Imm₇] == 1)

IP = Ca + Constant

Execution Units: Branch

Exceptions: none

Notes:

BCC –Branch if Carry Clear

BCC Rm, Rn, label

Description:

Branch if the carry would be set when comparing the first source operand to the second. The first operand is in a register, the second in a register or an immediate value. Both operands are treated as unsigned integer values. The displacement is relative to the address of the branch instruction.

A postfix instruction containing an immediate value may follow the branch instruction, in which case the immediate is used instead of Rb. Rb should be set to zero.

Instruction Format: B, BL

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}		Rb ₅		Ra ₅		0 ₃		Lk ₂		1	45 ₇	

Clock Cycles: 4

BCS –Branch if Carry Set

BCS Rm, Rn, label

Description:

This is an alternate mnemonic for the [BLO](#) instruction. Branch if the carry would be set because of the comparison of the first operand to the second. The first operand is in a register, the second in a register or an immediate value. Both operands are treated as unsigned integer values. The displacement is relative to the address of the branch instruction.

A postfix instruction containing an immediate value may follow the branch instruction, in which case the immediate is used instead of Rb. Rb should be set to zero.

Instruction Format: B, LB

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}				Rb ₅		Ra ₅		0 ₃		Lk ₂	1	44 ₇

Clock Cycles: 4

BGE –Branch if Greater Than or Equal

BGE Rm, Rn, label

Description:

Branch if the first source operand is greater than or equal to the second. The first operand is in a register, the second in a register or an immediate value. Both operands are treated as signed integer values. The displacement is relative to the address of the branch instruction.

A postfix instruction containing an immediate value may follow the branch instruction, in which case the immediate is used instead of Rb. Rb should be set to zero.

Instruction Format: B

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}				Rb ₅		Ra ₅		0 ₃		Lk ₂	1	41 ₇

Clock Cycles: 4

BGEU –Branch if Unsigned Greater Than or Equal

BGEU Rm, Rn, label

Description:

Branch if the first source operand is greater than or equal to the second. The first operand is in a register, the second in a register or an immediate value. Both operands are treated as unsigned integer values. The displacement is relative to the address of the branch instruction.

A postfix instruction containing an immediate value may follow the branch instruction, in which case the immediate is used instead of Rb. Rb should be set to zero.

Instruction Format: B, LB

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}				Rb ₅		Ra ₅		0 ₃		Lk ₂	1	45 ₇

Clock Cycles: 4

BEQ –Branch if Equal

BEQ Ra, Rb, label

Description:

Branch if two source operands are equal. The first operand is in a register, the second in a register or an immediate value. Both operands are treated as integer values. The displacement is relative to the address of the branch instruction.

A postfix instruction containing an immediate value may follow the branch instruction, in which case the immediate is used instead of Rn. Rn should be set to zero.

Formats Supported: B, LB

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}			Rb ₅		Ra ₅		0 ₃		Lk ₂		1	38 ₇

31	23	22	18	17	13	12	10	9	8	7	6	0
Target _{9..1}			Rb ₅		Ra ₅		0 ₃		Lk ₂		0	38 ₇

Clock Cycles: 4

BNE –Branch if Not Equal

BNE Rm, Rn, label

Description:

Branch if two source operands are not equal. The first operand is in a register, the second in a register or an immediate value. Both operands are treated as integer values. The displacement is relative to the address of the branch instruction.

A postfix instruction containing an immediate value may follow the branch instruction, in which case the immediate is used instead of Rn. Rn should be set to zero.

Instruction Format: B, LB

47	23	22	18	17	13	12	10	9	8	7	6	0
Target _{25..1}				Rb ₅		Ra ₅		0 ₃		Lk ₂	1	39 ₇

Clock Cycles: 4

BRA – Branch Always

Description:

This instruction always branches to the target address. The target address range is $\pm 256\text{GB}$.

Formats Supported: BSR

31	23	22	10	9	8	7	6	0
Target _{9..1}			Target _{22..10}			0 ₂	0	20h ₇

Formats Supported: LBSR

47	23	22	10	9	8	7	6	0
Target _{25..1}			Target _{38..26}			0 ₂	1	20h ₇

Operation:

$$\text{IP} = \text{IP} + \text{Constant}$$

Execution Units: Branch

Exceptions: none

Notes:

BSR – Branch to Subroutine

Description:

This instruction always jumps to the target address. The address of the next instruction is stored in a link register. The target address range is $\pm 256\text{GB}$.

Formats Supported: BSR

31	23	22	10	9	8	7	6	0
Target _{9..1}			Target _{22..10}			Lk ₂	0	20h ₇

Formats Supported: LBSR

47	23	22	10	9	8	7	6	0
Target _{25..1}			Target _{38..26}			Lk ₂	1	20h ₇

Operation:

Lk = next IP

IP = IP + Constant

Execution Units: Branch

Exceptions: none

Notes:

JMP – Jump to Target

Description:

This instruction always jumps to the target address. The target address is the sum of a register and an immediate constant shift left four times.

Instruction Format: JSR

31 30	29 26	25	17	16	12	11 9	8 7	6	0
Fmt ₂	Pr ₄	Immediate _{15..7}	Ra ₅	Im _{6..4}	0 ₂	36 ₇			

Operation:

Lk = next IP

IP = IP = sign extend (Constant)

Execution Units: Branch

Exceptions: none

Notes:

JSR – Jump to Subroutine

Description:

This instruction always jumps to the target address. The target address is the sum of a register and an immediate constant shift left four times. The address of the next instruction is stored in a link register.

Instruction Format: JSR

31	30	29	26	25	17	16	12	11	9	8	7	6	0
Fmt ₂	Pr ₄	Immediate _{15..7}				Ra ₅		Im _{6..4}		Lk ₂		36 ₇	

Operation:

Lk = next IP

IP = IP = sign extend (Constant)

Execution Units: Branch

Exceptions: none

Notes:

NOP – No Operation

NOP

Description:

This instruction does not perform any operation.

Instruction Format:

15	8	7	6	0
0xFF ₈	0	127 ₇		

31	8	7	6	0
0xFFFFF ₈	1	127 ₇		

RTD – Return from Subroutine and Deallocate

Description:

This instruction returns from a subroutine by transferring program execution to the address stored in a link register. Additionally, the stack pointer is incremented by the amount specified. The const field is shifted left four times before use.

Formats Supported: RTS

15	11	10 9	8 7	6	0
Const ₅	2 ₂	Lk ₂	35 ₇		

Operation:

Execution Units: Branch

Exceptions: none

Notes:

Return address prediction hardware may make use of the RTS instruction.

RTE – Return from Exception

Description:

This instruction returns from an exception routine by transferring program execution to the address stored in an internal stack. The const field is shifted left once before use. This instruction may perform a two-up level return.

Formats Supported: RTS

15	11	10 9	8 7	6	0
Const ₅	1 ₂	0 ₂	35 ₇		

Formats Supported: RTS – Two up level return.

15	11	10 9	8 7	6	0
Const ₅	1 ₂	1 ₂	35 ₇		

Operation:

Optionally pop the status register and program counter from the internal stack. Add Const wydes to the program counter. If returning from an application trap the status register is not popped from the stack.

Execution Units: Branch

Exceptions: none

Notes:

RTS – Return from Subroutine

Description:

This instruction returns from a subroutine by transferring program execution to the address calculated as the sum of a link register and a constant. The const field is shifted left once before use.

Formats Supported: RTS

15	11	10 9	8 7	6	0
Const ₅	0 ₂	Lk ₂	35 ₇		

Operation:

Execution Units: Branch

Exceptions: none

Notes:

Return address prediction hardware may make use of the RTS instruction.

System Instructions

BRK – Break

Description:

This instruction initiates the processor debug routine. The processor enters debug mode. The cause code register is set to indicate execution of a BRK instruction. Interrupts are disabled. The instruction pointer is reset to the contents of tvec[3] and instructions begin executing. There should be a jump instruction placed at the break vector location. The address of the BRK instruction is stored in the EIP.

Instruction Format: BRK

15	7	6	0
00 ₉	00h ₇		

Operation:

PUSH SR
PUSH IP
IP = tvec[3]

Execution Units: Branch

Clock Cycles:

Exceptions: none

Notes:

IRQ – Generate Interrupt

Description:

Generate interrupt. This instruction invokes the system exception handler. The return address is stored in the EIP register (code address register #8 to 15).

The return address stored is the address of the interrupt instruction, not the address of the next instruction. To call system routines use the [SYS](#) instruction.

The level of the interrupt is checked and if the interrupt level in the instruction is less than or equal to the current interrupt level then the instruction will be ignored.

Instruction Format:

31	29	28	25	24	19	18		7	6	0
Lvl ₃	Pr ₄			~ ₆			Cause ₁₂			112 ₇

Operation:

PUSH SR

PUSH IP

CAUSE = Cause₁₂

IP = tvec[3]

MEMDB – Memory Data Barrier

Description:

All memory accesses before the MEMDB command are completed before any memory accesses after the data barrier are started.

Instruction Format:

15	8	6	0
1 ₉	114 ₇		

Clock Cycles: 1

Execution Units: Memory

MEMSB – Memory Synchronization Barrier

Description:

All instructions before the MEMSB command are completed before any memory access is started.

Instruction Format:

15	8	6	0
2 ₉	114 ₇		

Clock Cycles: 1

Execution Units: Memory

PFI – Poll for Interrupt

Description:

The poll for interrupt instruction polls the interrupt status lines and performs an interrupt service if an interrupt is present. Otherwise, the PFI instruction is treated as a NOP operation. Polling for interrupts is performed by managed code. PFI provides a means to process interrupts at specific points in running software. Rt is loaded with the cause code in the low order twelve bits, and the interrupt level in bits twelve to fourteen of the register.

Instruction Format: OSR2

15 12	11	7	6	0
0 ₄	Rt ₅	115 ₇		

Clock Cycles: 1 (if no exception present)

Operation:

if (irq \neq 0)
 Rt[11:0] = cause code
 Rt[14:12] = irq level
 PMSTACK = (PMSTACK << 4) | 6
 CAUSE = Const₁₂
 EIP = IP
 IP = tvec[3]

Execution Units: Branch

SYNC -Synchronize

Description:

All instructions for a particular unit before the SYNC are completed and committed to the architectural state before instructions of the unit type after the SYNC are issued. This instruction is used to ensure that the machine state is valid before subsequent instructions are executed.

Instruction Format:

15	8	6	0
0 ₉	114 ₇		

SYS – System Call

Description:

Perform a system call. Interrupts are disabled. The instruction pointer is reset to the contents of tvec[3] and instructions begin executing. There should be a jump instruction placed at the break vector location. The address of the SYS instruction is stored in the EIP register.

Instruction Format: BRK

15	7	6	0
Callno ₉		0 ₇	

Operation:

PUSH SR onto internal stack
PUSH IP onto internal stack
IP = tvec[3]

Execution Units: Branch

Clock Cycles:

Exceptions: none

Notes:

WFI – Wait for Interrupt

Description:

The WFI instruction waits for an external interrupt to occur before proceeding. While waiting for the interrupt, the processor clock is slowed down or stopped placing the processor in a lower power mode.

Instruction Format: WAIT

15	11	11	7	6	0
14	0	115 ₇			

Clock Cycles: 1 (if no exception present)

Execution Units: Branch

Macro Instructions

ENTER – Enter Routine

Description:

This instruction is used for subroutine linkage at entrance into a subroutine. First it pushes the frame pointer and return address onto the stack, next the stack pointer is loaded into the frame pointer, and finally the stack space is allocated. This instruction is code dense, replacing eight other instructions with a single instruction.

A maximum of 32MB may be allocated on the stack. An immediate postfix may not be used with this instruction. The stack and frame pointers are assumed to be r31 and r30 respectively.

Note that the constant must be a negative number and a multiple of sixteen.

Note that the instruction reserves room for two words in addition to the return address and frame pointer. One use for the extra words may to store exception handling information.

Note this instruction uses T0 as a temporary register.

Integer Instruction Format: RI

Operation:

SP = SP - 64
Memory[SP] = FP
T0 = LR0
Memory16[SP] = T0
Memory32[SP] = 0 ; zero out catch handler address
Memory48[SP] = 0
FP = SP
SP = SP + constant

LEAVE – Leave Routine

Description:

This instruction is used for subroutine linkage at exit from a subroutine. First it moves the frame pointer to the stack pointer deallocating any stack memory allocations. Next the frame pointer and return address are popped off the stack. The stack pointer is adjusted by the amount specified in the instruction. Then a jump is made to the return address. This instruction is code dense, replacing six other instructions with a single instruction. The stack pointer adjustment is multiplied by sixteen keeping the stack pointer word aligned. A five-bit constant multiplied by two is added to the link register to form the return address. This allows returning up to 64 bytes past the normal return address.

Instruction Format: LEAVE

31	12	11	7	6	0
Constant ₂₀				Cnst ₅	53 ₇

Operation:

SP = FP

FP = Memory[SP]

T0 = Memory16[SP]

LR0 = T0

SP = SP + 64 + Constant₂₀ * 16

IP = LR0 + Cnst₅ * 2

POP – Pop Registers from Stack

Description:

This instruction pops up to eight registers from the stack. Using a constant postfix all registers may be popped from the stack. One of two sets of registers may be popped. A0 to A2 and T0 to T4 OR T5 to T7 and S0 to S4.

Instruction Format: POP

15	8	7	6	0
Reglist ₈	G		55 ₇	

G	Bit	Reg	Bit	Reg	Bit	Reg
0	0	A0	17	S6	34	
	1	A1	18	S7	35	
	2	A2	19	A3	36	
	3	T0	20	A4	37	
	4	T1	21	A5	38	
	5	T2	22	A6	39	
	6	T3	23	S8	40	
	7	T4	24	S9		
1	8	T5	25	S10

	12	S1	29	FP		
	13	S2	30	ASP		
	14	S3	31	SSP		
	15	S4	32	HSP		
	16	S5	33	MSP		

Operation:

PUSH – Push Registers on Stack

Description:

This instruction pushes up to eight registers onto a stack. Using a constant postfix all registers may be saved on the stack. One of two sets of registers may be saved. A0 to A2 and T0 to T4 OR T5 to T7 and S0 to S4.

Instruction Format: PUSH

15	8	7	6	0
Reglist ₈	G			54 ₇

G	Bit	Reg	Bit	Reg	Bit	Reg
0	0	A0	17	S6	34

	13	S2	30	ASP		
	14	S3	31	SSP		
	15	S4	32	HSP		
	16	S5	33	MSP		

Operation:

$$SP = SP - N * 16$$

if (N > 3) Memory₁₆[SP+(N-4)*16] = Rd

if (N > 2) Memory₁₆[SP+(N-3)*16] = Rc

if (N > 1) Memory₁₆[SP+(N-2)*16] = Rb

if (N > 0) Memory₁₆[SP+(N-1)*16] = Ra

Modifiers

ATOM

Description:

Treat the following sequence of instructions as an “atom”. The instruction sequence is executed with interrupts disabled. Interrupts are disabled for up to eight instructions.

Disable interrupts for the following Cnt₃ instructions.

Instruction Format:

Instruction Format: ATOM

15	10	9	7	6	0
~ ₆	Cnt ₃	122 ₇			

Assembler Syntax:

Example:

```
ATOM 6
LOAD a0,[a3]
CMP t0,a0,a1
PEQ t0,"TTF"
STORE a2,[a3]
LDI a0,1
LDI a0,0
```

```
ATOM 4
LOAD a1,[a3]
ADD t0,a0,a1
MOV a0,a1
STORE t0,[a3]
```

PRED

Description:

Apply the predicate to following instructions according to a bit mask. The predicate may be applied to a maximum of seven instructions. Note that postfixes do not count as instructions.

Pred Modifier Scope	Mask Bit	
	0,1	Instruction zero
	2,3	Instruction one
	4,5	Instruction two
	6,7	Instruction three
	8,9	Instruction four
	10,11	Instruction five
	12,13	Instruction six

Mask Bit	Meaning
00	Always execute (ignore predicate)
01	Execute only if predicate is true
10	Execute only if predicate is false
11	Always execute (ignore predicate)

Instruction Format: REP

31	30	29	26	25		12	11	10	7	6		0
Fmt ₂		Pr ₄			Immediate _{13..0}		~		Pr ₄			121 ₇

Assembler Syntax:

After the instruction mnemonic the register containing the predicate flags is specified. Next a character string containing 'T' for True, 'F' for false, or 'I' for ignore for the next seven instructions is present.

Example:

```
PRED r2,"TTTTFFI" ; next three execute if true, three after execute if false, one after always execute
MUL r3,r4,r5      ; executes if True
ADD r6,r3,r7      ; executes if True
ADD r6,r6,#1234   ; executes if True
DIV r3,r4,r5      ; executes if FALSE
ADD r6,r2,r1      ; executes if FALSE
ADD r6,r6,#456    ; executes if FALSE
MUL r8,r9,r10     ; always executes
```

REP

Description:

This modifier indicates a short series of instructions to repeat while the loop counter condition is met. The repeat modifier includes instructions according to a count specified in the $ICnt_3$ field. The number of included instructions is one greater than $ICnt_3$. Up to eight instructions may be part of the repeat operation. The loop counter may be incremented or decremented for each repeat. Loop counter tests perform signed comparisons. The 12-bit immediate may be overridden with a constant postfix instruction. The constant postfix does not count as an instruction in the loop.

REP is limited to a 32-bit immediate value.

Context for the REP instruction is stored in a context buffer which must be saved and restored when the context changes or during interrupt processing.

Instruction Format: REP

31	30	29	26	25	14	13	12	10	9	7	6	0
Fmt ₂		Pr ₄		Immediate _{11..0}		D	ICnt ₃		Cnd ₃		120 ₇	

D	Meaning
0	Decrement loop counter
1	Increment loop counter

Cnd ₃	Loop Counter Test	
0h	Equal	LC == Imm
1h	Not equal	LC != Imm
2h	Signed less than	LC < Imm
3h	Signed less than or equal	LC <= Imm
4h	Signed greater than or equal	LC >= Imm
5h	Signed greater than	LC > Imm
6h	Bit clear	LC[imm] = 0
7h	Bit set	LC[imm] == 1

Assembler Syntax:

ROUND

Description:

Set the rounding mode for following three instructions. Note that postfixes do not count as instructions.

ROUND Modifier Scope	Mask Bit	
	0 to 2	Instruction zero
	3 to 5	Instruction one
	6 to 8	Instruction two

Instruction Format:

1513	1210	9	7	6	0
Rm ₃	Rm ₃	Rm ₃			116 ₇

Binary Float Rounding Modes

Rm3	Rounding Mode
000	Round to nearest ties to even
001	Round to zero (truncate)
010	Round towards plus infinity
011	Round towards minus infinity
100	Round to nearest ties away from zero
101	Reserved
110	Reserved
111	Use rounding mode in float control register

Assembler Syntax:

Example:

MPU Hardware

PIC – Programmable Interrupt Controller

Overview

The programmable interrupt controller manages interrupt sources in the system and presents an interrupt signal to the cpu. The PIC may be used in a multi-CPU system as a shared interrupt controller. The PIC can guide the interrupt to the specified core. If two interrupts occur at the same time the controller resolves which interrupt the cpu sees. While the CPU's interrupt input is only level sensitive the PIC may process interrupts that are either level or edge sensitive. the PIC is a 32-bit I/O device.

System Usage

There is just a single interrupt controller in the system. It supports 31 different interrupt sources plus a non-maskable interrupt source.

The PIC is located at an address determined by BAR0 in the configuration space.

Priority Resolution

Interrupts have a fixed priority relationship with interrupt #1 having the highest priority and interrupt #31 the lowest. Note that interrupt priorities are only effective when two interrupts occur at the same time.

Config Space

A 256-byte config space is supported. Most of the config space is unused. The only configuration is for the I/O address of the register set.

Regno	Width	R/W	Moniker	Description		
000	32	RO	REG_ID	Vendor and device ID		
004	32	R/W				
008	32	RO				
00C	32	R/W				
010	32	R/W	REG_BAR0	Base Address Register		
014	32	R/W	REG_BAR1	Base Address Register		
018	32	R/W	REG_BAR2	Base Address Register		
01C	32	R/W	REG_BAR3	Base Address Register		
020	32	R/W	REG_BAR4	Base Address Register

028	32	R/W				
02C	32	RO		Subsystem ID		
030	32	R/W		Expansion ROM address		
034	32	RO				
038	32	R/W		Reserved		
03C	32	R/W		Interrupt		
040 to	32	R/W		Capabilities area		

0FF						
-----	--	--	--	--	--	--

REG_BAR0 defaults to \$FEE20001 which is used to specify the address of the controller's registers in the I/O address space.

The controller will respond with a memory size request of 0MB (0xFFFFFFFF) when BAR0 is written with all ones. The controller contains its own dedicated memory and does not require memory allocated from the system.

Parameters

CFG_BUS defaults to zero

CFG_DEVICE defaults to six

CFG_FUNC defaults to zero

Config parameters must be set correctly. CFG device and vendors default to zero.

Registers

The PIC contains 40 registers spread out through a 256 byte I/O region. All registers are 32-bit and only 32-bit accessible. There are two different means to control interrupt sources. One is a set of registers that works with bit masks enabling control of multiple interrupt sources at the same time using single I/O accesses. The other is a set of control registers, one for each interrupt source, allowing control of interrupts on a source-by-source basis.

Regno	Access	Moniker	Purpose	
00	R	CAUSE	interrupt cause code for currently interrupting source	
04	RW	RE	request enable, a 1 bit indicates interrupt requesting is enabled for that interrupt, a 0 bit indicates the interrupt request is disabled.	
08	W	ID	Disables interrupt identified by low order five data bits.	
0C	W	IE	enables interrupt identified by low order five data bits	
10			reserved	
14	W	RSTE	resets the edge-sense circuit for edge sensitive interrupts, 1 bit for each interrupt source. This register has no effect on level sensitive sources. This register automatically resets to zero.	
18	W	TRIG	software trigger of the interrupt specified by the low order five data bits.	
20	W	ESL	The low bit for edge sensitivity selection. ESL and ESH combine to form a two bit select of the edge sensitivity.	
			ESH,EHL	Sensitivity
			00	level sensitive interrupt
			01	positive edge sensitive
			10	negative edge sensitive
11	either edge sensitive			
24	W	ESH	The high bit for edge sensitivity selection	
80	RW	CTRL0	control register for interrupt #0	
84	RW	CTRL1	control register for interrupt #1	
...		...		
FC	RW	CTRL31	control register for interrupt #31	

Control Register

All the control registers are identical for all interrupt sources, so only the first control register is described here.

Bits

0 to 7	CAUSE	The cause code associated with the interrupt; this register is copied to the cause register when the interrupt is selected.
8 to 10	IRQ	This register determines which signal lines of the cpu are activated for the interrupt. Signal lines are typically used to resolve priority.
16	IE	This is the interrupt enable bit, 1 enables the interrupt, 0 disables it. This is the same bit reflected in the RE register.
17	ES	This bit controls edge sensitivity for the interrupt 0 = level, 1 = pos. edge sensitive. This same bit is present in the ESL register.
18		reserved
19	IRQAR	Respond to an IRQ Ack cycle
20 to 23		reserved
24 to 29	CORE	Core number to select for interrupt processing
30 to 31		reserved

PIT – Programmable Interval Timer

Overview

Many systems have at least one timer. The timing device may be built into the cpu, but it is frequently a separate component on its own. The programmable interval timer has many potential uses in the system. It can perform several different timing operations including pulse and waveform generation, along with measurements. While it is possible to manage timing events strictly through software it is quite challenging to perform in that manner. A hardware timer comes into play for the difficult to manage timing events. A hardware timer can supply precise timing. In the test system there are two groups of four timers. Timers are often grouped together in a single component. The PIT is a 64-bit peripheral. The PIT while powerful turns out to be one of the simpler peripherals in the system.

System Usage

One programmable timer component, which may include up to 32 timers, is used to generate the system time slice interrupt and timing controls for system garbage collection. The second timer component is used to aid the paged memory management unit. There are free timing channels on the second timer component.

Each PIT is given a 64kB-byte memory range to respond to for I/O access. As is typical for I/O devices part of the address range is not decoded to conserve hardware.

PIT#1 is located at \$FFFFFFFFFEE4xxxx

PIT#2 is located at \$FFFFFFFFFEE5xxxx

Config Space

A 256-byte config space is supported. Most of the config space is unused. The only configuration is for the I/O address of the register set and the interrupt line used.

Regno	Width	R/W	Moniker	Description		
000	32	RO	REG_ID	Vendor and device ID		
004	32	R/W				
008	32	RO				
00C	32	R/W				
010	32	R/W	REG_BAR0	Base Address Register		
014	32	R/W	REG_BAR1	Base Address Register		
018	32	R/W	REG_BAR2	Base Address Register		
01C	32	R/W	REG_BAR3	Base Address Register		
020	32	R/W	REG_BAR4	Base Address Register		
024	32	R/W	REG_BAR5	Base Address Register		
028	32	R/W				
02C	32	RO		Subsystem ID		
030	32	R/W		Expansion ROM address		
034	32	RO				
038	32	R/W		Reserved		

03C	32	R/W		Interrupt		
040 to 0FF	32	R/W		Capabilities area		

REG_BAR0 defaults to \$FEE40001 which is used to specify the address of the controller's registers in the I/O address space. Note for additional groups of timers the REG_BAR0 must be changed to point to a different I/O address range. Note the core uses only bits determined by the address mask in the address range comparison. It is assumed that the I/O address select input, cs_io, will have bits 24 and above in its decode and that a 64kB page is required for the device, matching the MMU page size.

The controller will respond with a mask of 0x00FF0000 when BAR0 is written with all ones.

Parameters

CFG_BUS defaults to zero

CFG_DEVICE defaults to four

CFG_FUNC defaults to zero

CFG_ADDR_MASK defaults to 0x00FF0000

CFG_IRQ_LINE defaults to 29

Config parameters must be set correctly. CFG device and vendors default to zero.

Parameters

NTIMER: This parameter controls the number of timers present. The default is eight. The maximum is 32.

BITS: This parameter controls the number of bits in the counters. The default is 48 bits. The maximum is 64.

PIT_ADDR: This parameter sets the I/O address that the PIT responds to. The default is \$FEE40001.

PIT_ADDR_ALLOC: This parameter determines which bits of the address are significant during decoding. The default is \$00FF0000 for an allocation of 64kB. To compute the address range allocation required, 'or' the value from the register with \$FF000000, complement it then add 1.

Registers

The PIT has 134 registers addressed as 64-bit I/O cells. It occupies 2048 consecutive I/O locations. All registers are read-write except for the current counts which are read-only. All registers all 64-bit accessible; all 64 bits must be read or written. Values written to registers do not take effect until the synchronization register is written.

Note the core may be configured to implement fewer timers in which case timers that are not implemented will read as zero and ignore writes. The core may also be configured to support fewer bits per count register in which case the unimplemented bits will read as zero and ignore writes.

Regno	Access	Moniker	Purpose
00	R	CC0	Current Count
08	RW	MC0	Max count
10	RW	OT0	On Time
18	RW	CTRL0	Control
20 to 7F8	Groups of four registers for timer #1 to #63
800	RW	USTAT	Underflow status
808	RZW	SYNC	Synchronization register
810	RW	IE	Interrupt enable
818	RW	TMP	Temporary register
820	RO	OSTAT	Output status
828	RW	GATE	Gate register
830	RZW	GATEON	Gate on register
838	RZW	GATEOFF	Gate off register

Control Register

This register contains bits controlling the overall operation of the timer.

Bit		Purpose
0	LD	setting this bit will load max count into current count, this bit automatically resets to zero.
1	CE	count enable, if 1 counting will be enabled, if 0 counting is disabled and the current count register holds its value. On counter underflow this bit will be reset to zero causing the count to halt unless auto-reload is set.
2	AR	auto-reload, if 1 the max count will automatically be reloaded into the current count register when it underflows.
3	XC	external clock, if 1 the counter is clocked by an external clock source. The external clock source must be of lower frequency than the clock supplied to the PIT. The PIT contains edge detectors on the external clock source and counting occurs on the detection of a positive edge on the clock source. This bit is forced to 0 for timers 4 to 31.
4	GE	gating enable, if 1 an external gate signal will also be required to be active high for the counter to count, otherwise if 0 the external gate is ignored. Gating the counter using the external gate may allow pulse-width measurement. This bit is forced to 0 for timers 4 to 31.
5 to 63	~	not used, reserved

Current Count

This register reflects the current count value for the timer. The value in this register will change by counting downwards whenever a count signal is active. The current count may be automatically reloaded at underflow if the auto reload bit (bit #2) of the control byte is set. The current count may also be force loaded to the max count by setting the load bit (bit #0) of the counter control byte.

Max Count

This register holds onto the maximum count for the timer. It is loaded by software and otherwise does not change. When the counter underflows the current count may be automatically reloaded from the max count register.

On Time

The on-time register determines the output pulse width of the timer. The timer output is low until the on-time value is reached, at which point the timer output switches high. The timer output remains high until the counter reaches zero at which point the timer output is reset back to zero. So, the on time reflects the length of time the timer output is high. The timer output is low for max count minus the on-time clock cycles.

Underflow Status

The underflow status register contains a record of which timers underflowed.

Writing the underflow register clears the underflows and disable further interrupts where bits are set in the incoming data. Interrupt processing should read the underflow register to determine which timers underflowed, then write back the value to the underflow register.

Synchronization Register

The synchronization register allows all the timers to be updated simultaneously. Values written to timer registers do not take effect until the synchronization register is written. The synchronization register must be written with a '1' bit in the bit position corresponding to the timer to update. For instance, writing all one's to the sync register will cause all timers to be updated. The synchronization register is write-only and reads as zero.

Interrupt Enable Register

Each bit of the interrupt enable register enables the interrupt for the corresponding timer. Interrupts must also be globally enabled by the interrupt enable bit in the config space for interrupts to occur. A '1' bit enables the interrupt, a '0' bit value disables it.

Temporary Register

This is merely a register that may be used to hold values temporarily.

Output Status

The output status register reflects the current status of the timers output (high or low). This register is read-only.

Gate Register

The internal gate register is used to temporarily halt or resume counting for the timer corresponding to the bit position of this register. Writing a value to this register will turn on all timers where there is a '1' bit in the value and turn off all timers where there is a '0' bit in the value.

Gate On Register

The internal gate 'on' register is used to resume counting for the timer corresponding to the bit position of this register. Writing a value to this register will turn on all timers where there is a '1' bit in the value. Where there is a '0' in the value the timer will not be affected. This register reads as zero.

Gate Off Register

The internal gate 'off' register is used to halt counting for the timer corresponding to the bit position of this register. Writing a value to this register will turn off all timers where there is a '1' bit in the value. Where there is a '0' in the value the timer will not be affected. This register reads as zero.

Programming

The PIT is a memory mapped i/o device. The PIT is programmed using 64-bit load and store instructions (LDO and STO). Byte loads and stores (LDB, STB) may be used for control register access. It must reside in the non-cached address space of the system.

Interrupts

The core is configured use interrupt signal #29 by default. This may be changed with the CFG_IRQ_LINE parameter. Interrupts may be globally disabled by writing the interrupt disable bit in the config space with a '1'. Individual interrupts may be enabled or disabled by the setting of the interrupt enable register in the I/O space.
